

PATENT APPLICATION**EQUIPMENT AND METHODS FOR MANUFACTURING CIGARETTES****FIELD OF THE INVENTION**

The present invention relates to smoking articles, and in particular, to equipment, materials and techniques used for the manufacture of those smoking articles. More specifically, the present invention relates to the manufacture of cigarette rods, and in particular, to systems and methods for applying an additive material to desired locations of wrapping materials of cigarettes in an efficient, effective and desired manner.

BACKGROUND OF THE INVENTION

Smoking articles, such as cigarettes, have a substantially cylindrical rod-shaped structure and include a charge, roll, or column of smokable material, such as shredded tobacco, surrounded by a paper wrapper, to form a "cigarette rod," "smokable rod" or a "tobacco rod." Normally, a cigarette has a cylindrical filter element aligned in an end-to-end relationship with the tobacco rod. Typically, a filter element comprises plasticized cellulose acetate tow circumscribed by a paper material known as "plug wrap." Certain cigarettes incorporate filter elements comprising, for example, activated charcoal particles. Typically, the filter element is attached to one end of the tobacco rod using a circumscribing wrapping material known as "tipping paper."

A cigarette is used by a smoker by lighting one end of that cigarette, and burning the tobacco rod. The smoker then receives mainstream smoke into his or her mouth by drawing on the opposite end of the cigarette. During the time that the cigarette is not being drawn upon by the smoker, the cigarette remains burning.

Numerous attempts have been made to control the manner that a cigarette burns when the cigarette is not being drawn upon. For example, cigarette papers have been treated with various materials to cause cigarettes incorporating those papers to self extinguish during periods when those cigarettes are lit but are not being actively puffed. Certain treatment methods have involved applying materials to the paper in circumferential bands or longitudinal stripes, creating areas that affect the burn rate of cigarettes incorporating that cigarette papers. See, for example,

1 U.S. Patent Nos. 3,030,963 to Cohn; 4,146,040 to Cohn; 4,489,738 to Simon; 4,489,650 to
2 Weinert; and 4,615,345 to Durocher; U.S. Patent Application 2002/0185143 to Crooks et al.;
3 U.S. Patent Application 2003/0145869 to Kitao et al.; U.S. Patent Application 2003/0150466 to
4 Kitao et al.; and U.S. Patent Application Serial No. 09/892,834, filed June 27, 2001. In addition,
5 numerous references disclose applying films to the paper wrapping materials of tobacco rods.
6 See, for example, U.S. Patent Nos. 1,909,924 to Schweitzer; 4,607,647 to Dashley; and
7 5,060,675 to Milford et al.; and U.S. Patent Application 2003/0131860 to Ashcraft et al.

8 “Banded” paper wrapping materials that are used for cigarette manufacture possess
9 segments defined by the composition, location, and properties of the various materials within
10 those wrapping materials. Numerous references contain disclosures suggesting various banded
11 wrapping material configurations. See, for example, U.S. Patent Nos. 1,996,002 to Seaman;
12 2,013,508 to Seaman; 4,452,259 to Norman et al.; 5,417,228 to Baldwin et al.; 5,878,753 to
13 Peterson et al.; 5,878,754 to Peterson et al.; and 6,198,537 to Bokelman et al.; and PCT WO
14 02/37991. Methods for manufacturing banded-type wrapping materials also have been
15 disclosed. See, for example, U.S. Patent Nos. 4,739,775 to Hampl, Jr. et al.; and 5,474,095 to
16 Allen et al.; and PCT WO 02/44700 and PCT WO 02/055294. Some of those references
17 describe banded papers having segments of paper, fibrous cellulosic material, or particulate
18 material adhered to a paper web. See, U.S. Patent Nos. 5,263,999 to Baldwin et al.; 5,417,228 to
19 Baldwin et al.; and 5,450,863 to Collins et al.; and U.S. Patent Application 2002/0092621 to
20 Suzuki. Methods for manufacturing cigarettes having treated wrapping materials are set forth in
21 U.S. Patent Nos. 5,191,906 to Myracle, Jr. et al. and PCT WO 02/19848.

22 Additive materials can be applied to cigarette paper wrapping materials during the time
23 that those wrapping materials are being used for cigarette manufacture (i.e., in a so-called “on-
24 line” fashion). However, water-based formulations incorporating those additives, and the paper
25 wrappers to which the additives are applied, have a tendency to remain wet when the additive-
26 treated wrapper reaches the garniture section of the cigarette making machine. Consequently, for
27 example, the additive materials that are applied to a paper web tend to rub off of the paper and
28 onto components of the finger rail assembly that is located near the garniture end of the suction
29 rod conveyor of the cigarette making machine, and onto the tongue and folder components that
30 are located in the garniture region of the cigarette making machine. A build-up of additive
31 material on certain regions of the cigarette making machine can cause cigarette rod formation

1 problems, paper breaks, and machine downtime for cleaning. Such an undesirable tendency for
2 additive materials to transfer from the paper web to surfaces of the cigarette machine is increased
3 with increasing speed of manufacture of the continuous cigarette rod.

4 Several references have proposed modifications to the garniture regions of cigarette
5 making machines. Several of those references propose introducing certain substances into a
6 cigarette making machine during cigarette rod manufacture. For example, U.S. Patent No.
7 4,186,754 to Labbe discloses feeding water or alcohol to the surface of the tongue which
8 contacts the stream of a particular type of tobacco in order address concerns of gummy
9 substances that reportedly build up on that tongue. U.S. Patent No. 4,409,995 to Nichols
10 discloses applying a flavorant in particulate or liquid form to a cigarette rod through the tongue
11 region of a cigarette making machine. U.S. Patent No. 4,619,276 to Albertson et al. discloses
12 applying foamed flavorant to a cigarette rod through the tongue region of a cigarette making
13 machine. U.S. Patent No. 4,899,765 to Davis et al. discloses a process for introducing liquid into
14 the garniture tongue in liquid outlet openings.

15 It would be highly desirable to provide cigarettes having predetermined patterns of
16 additive materials (e.g., as bands) applied in desired locations to the wrapping materials of those
17 cigarettes, particularly using on-line processes during cigarette manufacture. It also would be
18 desirable to apply additive materials to a continuous web of a wrapping material of a tobacco rod
19 in an efficient and effective manner during the manufacture of that tobacco rod. It also would be
20 desirable to ensure that the wrapping material so treated with additive material meets standards
21 of quality desired by the manufacturer of those tobacco rods. It also would be desirable to
22 provide a method for minimizing or preventing transfer of an additive material on a paper web to
23 a cigarette making machine surface; and it also would be desirable that such method operate
24 effectively and be easily implemented within a conventional automated cigarette making
25 machine of the type used to produce commercial quantities of cigarettes.

26 27 **SUMMARY OF THE INVENTION**

28 The present invention provides systems, apparatus, and methods for manufacturing
29 smoking articles, such as cigarettes. Certain preferred aspects of the present invention relate to
30 manners and methods for transferring additive material to, and retaining an additive material on
31 desired locations of, a wrapping material suitable for use for smoking article manufacture (e.g.,

1 paper wrapping web) when manufacturing smoking articles from those materials using a
2 cigarette making machine. That is, preferred aspects of the present invention comprise various
3 embodiments of an apparatus for applying an additive material (e.g., as an adhesive-type of
4 formulation) to a continuous advancing strip of a paper web within a region of an automated
5 cigarette making machine system (e.g., a machine designed to produce a continuous cigarette
6 rod). In the highly preferred aspects of the present invention, an additive material is applied to a
7 paper web in an on-line fashion (i.e., using a cigarette making machine or a component of a
8 cigarette making machine assembly during cigarette manufacturing process). In the most highly
9 preferred aspects of the present invention, the automated cigarette making machine can operate
10 so as to apply a desired additive material, in a desired amount, in a desired configuration, in a
11 desired location, on a continuous strip of paper wrapping material used for the manufacture of a
12 continuous cigarette rod; which strip of paper wrapping material is supplied (and hence the
13 continuous cigarette rod is manufactured) at speeds exceeding about 400 meters per minute.

14 Certain cigarette making apparatus and systems of the present invention are characterized
15 as single component systems. A continuous paper web is provided from a source (e.g., a bobbin)
16 associated with a component of such a system (e.g., an unwind spindle assembly of that system).
17 Tobacco filler and components for manufacturing a continuous cigarette rod from the tobacco
18 filler and the continuous paper web are provided using the same component of that system (e.g.,
19 using an upwardly moving air stream coupled with a conveyor system and a garniture system,
20 respectively). Such cigarette making apparatus can be adapted to incorporate additive
21 application apparatus that provide ways to apply additive material (e.g., coating formulations) to
22 the continuous paper web in an on-line fashion.

23 Certain cigarette making apparatus and systems of the present invention are characterized
24 as multi-component systems, and in particular, two component systems. A continuous paper
25 web is provided from a source that is the first component of such a system. Tobacco filler and
26 components for manufacturing a continuous cigarette rod from the tobacco filler and the
27 continuous paper web supplied by the first component are provided using the second component
28 of that system. For preferred two component systems, the two components are independent,
29 stand alone units. Such cigarette making apparatus can be adapted to incorporate additive
30 application apparatus that provide ways to apply additive material (e.g., coating formulations) to
31 the continuous paper web in an on-line fashion.

1 In one aspect, the present invention relates to equipment and methods for applying an
2 additive material to a substrate, such as a paper web used as a wrapping material for cigarette
3 manufacture. Those equipment and methods are particularly suitable in connection with the
4 operation of an automated cigarette making machine, and for the purpose of applying a
5 predetermined pattern of additive material to a continuous strip of paper web. An additive
6 application apparatus includes a first roller adapted to receive the additive material (e.g., a
7 coating formulation in liquid form) and a second roller adjacent to the first roller adapted to
8 transfer the additive material from the first roller to the substrate (e.g., paper web). That
9 apparatus also includes an additive material reservoir adjacent to the first roller for containing the
10 additive material, and for supplying the additive material to the first roller. The additive material
11 so supplied is positioned within pockets, grooves or indentations within the roll face of the first
12 roller. For that apparatus, the roll face of the second roller is in roll contact with the roll face of
13 the first roller in one location, and the roll face of the second roller is in contact with the paper
14 web in another location; thus allowing for a predetermined transfer of additive material in a two-
15 step manner. That is, when the additive material is supplied to pockets within the roll face of the
16 first roller, that additive material is transferred to the roll face of the second roller; and when the
17 second roller contacts the advancing paper web, the additive material is transferred from the roll
18 face of the second roller and applied to the advancing paper web.

19 For the foregoing additive application apparatus, appropriate roll contact between the roll
20 faces of the respective rollers is facilitated by a pressure plate, or other suitable means for
21 ensuring contact of the second roller with the first roller. As such, the first roller is moved, or
22 otherwise arranged or positioned, into operative rotating engagement with the second roller.
23 Thus, in certain embodiments, such as when the first and second rollers both are located on the
24 same side of the paper web, and when the first and second rollers are in appropriate roll contact,
25 the additive material is transferred from the first roller to the second roller in virtually the same
26 type of pattern as the pattern dictated by the location the pockets on the first roller. Contact of
27 the second roller with the paper web is provided using a roller lift bracket, or other suitable
28 means for facilitating contact of the second roller with the paper web. The roller lift bracket
29 includes a plurality of guide rollers, and the bracket is movable (e.g., preferably is slidable up
30 and down), so as to cause movement of those rollers into rotating roll contact with the paper web
31 and the paper web into contact with the second roller. Thus, when the paper web contacts the

1 second roller, the additive material is transferred from the second roller to the paper web in
2 essentially the same pattern as the pattern dictated by the location of the pockets on the first
3 roller (i.e., the pattern corresponds to the pattern of the pockets on the roll face of the first roller).
4 As such, a suitable method for applying additive material to a web of wrapping material, most
5 preferably in an on-line fashion, is provided.

6 In another embodiment of an additive application apparatus, additive material (e.g., a
7 coating formulation in paste form) is applied to a substrate (e.g., a paper web) using a system that
8 employs a first roller adapted to (i) receive an additive material from an additive material
9 reservoir, and (ii) apply that additive material to the substrate. Preferably, the first roller
10 comprises a plurality of pockets, grooves or indentations that are aligned or arranged in the form
11 of a pattern on the roll face of that roller. When the additive material is supplied to the first
12 roller, a predetermined amount of the additive material is contained in each of the plurality of
13 pockets. A second roller is in roll contact with the first roller, and the paper web passes through
14 the location or region where those two rollers make roll contact. Such roll contact facilitates
15 transfer of the additive material from the first roller to the paper web.

16 For the foregoing additive application apparatus, the second roller is connected to the
17 roller lift bracket and is thus positioned on the side of the paper web opposite the first roller. The
18 roller lift bracket preferably is movable, and as such provides a means to cause movement of the
19 second roller into, and out of, rotating contact with both the paper web and the first roller. In this
20 manner, the roller lift bracket provides both (i) a way to provide contact of the second roller with
21 the first roller, and (ii) a way to provide contact of the second roller with the paper web. Thus,
22 when the paper web comes into contact between the first and second rollers in the nip region or
23 location between those rollers, the additive material is transferred from the first roller to the
24 paper web in essentially the same pattern as the pattern dictated by the location of the pockets on
25 the first roller (i.e., the pattern corresponds to the pattern of the pockets on the roll face of the
26 first roller). As such, a suitable method for applying additive material to a web of wrapping
27 material, most preferably in an on-line fashion, is provided.

28 Another additive application apparatus includes a first roller adapted to receive the
29 additive material (e.g., a coating formulation in liquid form) and a second roller adjacent to the
30 first roller adapted to transfer the additive material from the first roller to a substrate (e.g.,
31 continuous advancing paper web). That apparatus also includes an additive material reservoir

1 adjacent to the first roller for containing the additive material, and for supplying the additive
2 material to the first roller. The additive material so supplied is positioned on the roll face of the
3 first roller. For that apparatus, the roll faces of protruding dies extending from the second roller
4 are in roll contact with the roll face of the first roller in one location; and the roll faces of the
5 protruding dies of the second roller are in contact with the paper web in another location; thus
6 allowing for a predetermined transfer of additive material in a two-step manner. That is, when
7 the additive material is supplied to the roll face of the first roller, that additive material is
8 transferred to the roll face of the protruding dies of the second roller; and when those dies
9 possessing additive material on their roll faces contact the advancing paper web, the additive
10 material is transferred from the roll face of the protruding dies of the second roller and applied to
11 the advancing paper web. As such, a suitable method for applying additive material to a web of
12 wrapping material, most preferably in an on-line fashion, is provided.

13 Another additive application apparatus includes a first roller adapted to receive the
14 additive material (e.g., a coating formulation in liquid form) on at least a portion of its roll face, a
15 second roller adjacent to the first roller adapted to receive the additive material to at least a
16 portion of its roll face, and an application roller adapted to (i) receive the additive material to
17 desired locations on the roll face thereof from the roll face of the second roller, and (ii) apply that
18 additive material to a substrate (e.g., continuous advancing paper web). That apparatus also
19 includes an additive material reservoir adjacent to the first roller for containing the additive
20 material, and for supplying the additive material to a desired location of the roll face of the first
21 roller (e.g., a continuous groove circumscribing a portion of the roll face of that first roller). As
22 such, the additive material so supplied is continuously positioned on a predetermined region of
23 the roll face of the first roller; and as a result of the roll interaction of the first and second rollers,
24 additive material is applied to a predetermined region of the roll face of the second roller. The
25 roll faces of protruding dies extending from the application roller are in roll contact with the roll
26 face of the second roller in one location; and the roll faces of the protruding dies of the
27 application roller are in contact with the paper web in another location. Thus, there is provided a
28 manner or method for carrying out a predetermined transfer of additive material in a multi-step
29 manner. That is, additive material is supplied to the roll face of a second roller as a result of roll
30 interaction of a first roller and that second roller, and that additive material on the roll face of the
31 second roller is transferred to predetermined locations on the roll face of the application roller.

1 When those locations of the application roller (e.g., those dies possessing additive material on
2 their roll faces) subsequently contact the advancing paper web, the additive material is
3 transferred from the roll face of the application roller and applied to the advancing paper web.
4 As such, a suitable method for applying additive material to a web of wrapping material, most
5 preferably in an on-line fashion, is provided.

6 Another additive application apparatus includes a first roller adapted to receive the
7 additive material (e.g., a coating formulation in liquid form) and adapted to transfer the additive
8 material to a substrate (e.g., a continuous advancing paper web). The paper web passes between
9 the roll faces of the first roller and a second roller. That apparatus also includes an additive
10 material reservoir adjacent to the first roller for containing the additive material, and for
11 supplying the additive material to the first roller. The additive material so supplied is positioned
12 on the roll face of the first roller. For that apparatus, the roll faces of protrusions or cams
13 extending from the second roller are in roll contact with the roll face of the first roller, and the
14 paper web passes between those roll faces such that both rollers are periodically in contact with
15 the paper web; thus allowing for a predetermined transfer of additive material to the paper web
16 from the roll face of the first roller when the roll faces of the protruding cams of the second roller
17 cause the application of force to the paper web. That is, when the additive material is supplied to
18 the roll face of the first roller, that additive material is transferred to predetermined locations on
19 the surface of the paper web when the protruding cams of the second roller cause the paper web
20 to be pushed against the roll face of the first roller. As such, a suitable method for applying
21 additive material to a web of wrapping material, most preferably in an on-line fashion, is
22 provided.

23 The present invention, in another aspect, relates to a system useful for retaining on a
24 paper web an additive material that has been applied to that paper web. The additive material
25 can be a material that is applied to the paper web in a previous processing step, such as using
26 gravure printing techniques (e.g., using so-called "off-line" techniques), or while that paper web
27 is being used for the manufacture of cigarettes within a cigarette making machine (e.g., using on-
28 line techniques). The system most preferably is located in the garniture entrance region of the
29 cigarette making machine, and particularly in the finger rail region of the cigarette making
30 machine. The system comprises a finger rail assembly and a garniture entrance cone, which are
31 located in a region of the cigarette making machine adapted to receive a continuous paper web.

1 The paper web is advanced between the lower region of the finger rail assembly and the upper
2 region of the garniture entrance cone. The system includes at least one air chamber (e.g.,
3 preferably each finger rail of the finger rail assembly includes an air chamber) located above the
4 advancing paper web and a supply of pressurized or compressed gas (e.g., air) is fed into that air
5 chamber (e.g., a manifold or tubular channel). The air chamber includes a plurality of air
6 distribution outlets or air passageways directed toward the lower surface of the system, and as
7 such, air flows out of the air chamber. When a high velocity stream of air exits the air
8 distribution outlets and is directed generally downward, a zone of air turbulence preferably is
9 created above the advancing paper web. That turbulence provides downward force that
10 maintains the paper web a distance away from (e.g., spaced from) the finger rail assembly of the
11 cigarette making machine. As a result, the additive material is retained on the paper web, and
12 undesirable transfer of the additive material to the finger rail components of the cigarette making
13 machine (and other regions of the cigarette making machine) is minimized, avoided or
14 prevented.

15 The present invention, in another aspect, relates to another system useful for retaining on
16 a paper web an additive material that has been applied to that paper web. That system
17 encompasses modification of a garniture entrance cone (which is designed to be positioned
18 below the advancing paper web within a cigarette making machine). An entrance cone of one
19 aspect of the present invention is adapted to possess an air chamber. That air chamber (e.g.,
20 manifold) is adapted to receive a flow or stream of gas (e.g., air) from a supply of pressurized or
21 compressed air. Two air channels, both providing air outlets, or other suitably adapted air
22 distribution means, are directed generally longitudinally, and are designed so as to provide a flow
23 of air generally upwardly and generally outwardly. As a result, for each of opposing edges of the
24 paper web (i.e., the right and left sides of the paper web relative to the longitudinal axis of that
25 web) that pass over that entrance cone, the stream of air exiting each channel creates a zone of
26 low air pressure zone between that paper web and the upper surface of the entrance cone. Each
27 of the paper web edges is affected by this low pressure zone, and each edge is urged toward the
28 entrance cone and away from the finger rail components of the cigarette making machine (and
29 other regions of the cigarette making machine). As a result, contact of the paper web and
30 additive material with certain components of the cigarette making machine is minimized,
31 avoided or prevented.

1 In one embodiment of the foregoing, an apparatus for the manufacture of cigarettes is
2 adapted to minimize, avoid or prevent transfer of an additive material applied to a paper web
3 from that paper web to surfaces of certain components of that apparatus. The apparatus includes
4 a finger rail assembly comprising a pair of finger rails positioned at the distal, or exit, end of a
5 suction rod conveyor system. The apparatus also includes a garniture entrance cone positioned
6 below the pair of finger rails, essentially as is conventional in a commercially available
7 automated cigarette making machine. The pair of finger rails and the garniture entrance cone are
8 adapted to receive between them a continuous strip of advancing paper web. In certain
9 circumstances, the advancing paper web has a predetermined pattern of additive material (e.g.,
10 bands) applied thereto. Each finger rail includes an air chamber, and the air chamber is adapted
11 to receive a high velocity stream of air. Each air chamber has a plurality of air distribution
12 outlets along its length directed generally downward toward the entrance cone. Those air
13 distribution outlets can be arranged in either a random or a predetermined pattern, preferably so
14 as to provide a turbulent flow of air below each finger rail. In the preferred embodiments, the
15 stream air and the design of the air outlet pattern provides for a relatively consistent air flow
16 from each of the various air distribution outlets. When the stream of air exits the air distribution
17 outlets, a zone of air movement (e.g., turbulence) is created above the advancing paper web; and
18 the action of that high velocity air flow acts to maintain the paper web a distance away from the
19 finger rails. Preferably, the entrance cone comprises an air chamber, and high velocity or
20 pressurized air is fed into that air chamber. Two air channels or slots, both providing air outlets,
21 or other suitably adapted air distribution means, are directed generally longitudinally, and are
22 designed so as to provide a flow of air generally upwardly and generally outwardly. When the
23 high velocity air exits the slots of the entrance, a zone of low pressure is created between the
24 paper web and the upper surface of the entrance cone. Each of the side edges of the paper web is
25 affected by this low pressure zone, and is urged toward the entrance cone upper surface and
26 away from the finger rails; and contact of the paper web with components of the finger rail
27 assembly is minimized, avoided or prevented. Thus, an improved method for the manufacture of
28 smoking articles, such as cigarettes, is provided.

29 In yet another aspect, the present invention relates to a system for controlling the heat to
30 which the web of wrapping material is subjected. That is, such a system can be used to control
31 the temperature (e.g., by heating or cooling) the web of paper wrapping material, and any

1 additive material that has been applied to that paper web. One suitable system is a radiant energy
2 system that utilizes electromagnetic radiation in the form of microwave radiation. In a highly
3 preferred embodiment, the moving continuous paper web is subjected to treatment using a
4 heating/cooling device (which most preferably is a radiant heating device) essentially
5 immediately after that paper web has additive material (e.g., a water-based coating formulation)
6 applied thereto.

7 The present invention, in one aspect, relates to a system for controlling, or registering, in
8 an on-line fashion, the location of the applied pattern (e.g., bands) of additive material on the
9 wrapping material to the location of that pattern on the smoking article that is manufactured. In
10 one embodiment, the application of each band is controlled relative to the speed at which the
11 cigarette making machine is operated; and the location of each band is timed to the operation of
12 the cutting device (e.g., flying knife) that cuts the continuous rod into cigarette rods of
13 predetermined length. In another embodiment, registration of patterns (e.g., bands) on a paper
14 web, and hence on predetermined locations on cigarettes, is provided using digital motion
15 control techniques that utilize a servo control system in combination with (i) digital encoders for
16 providing feedback of certain cigarette making machine operating parameters (e.g., such as
17 information regarding band positioning and continuous cigarette rod speed), and (ii) feedback
18 from a detector that responds to the presence of bands on the paper web.

19 In another aspect, the present invention relates an adapted automated cigarette making
20 apparatus of the type having a conveyor belt for tobacco filler supply, a garniture belt for
21 advancing a continuous strip of paper web, and a cutting knife for subdividing a continuous
22 cigarette rod into predetermined lengths; and all of the foregoing are operated using a single
23 power source (e.g., all of the foregoing are mechanically linked by belts and driven off of the
24 same main motor). The adapted apparatus is provided by disabling operation of the power
25 source, such as is accomplished by removing connection of operation of each of the conveyor
26 belt, the garniture belt and the cutting knife to that power source. Operation of the cutting knife
27 is adapted so as to be powered by a second power source (e.g., the motor of a servo system).
28 Operation of the garniture belt and the conveyor belt are provided by a third power source (e.g., a
29 motor of a servo system) that is independent of the second power source. As such, operation of
30 the garniture belt and conveyor belt are mechanically linked to one another. During operation of
31 the adapted apparatus, output signals from each of the second and third power sources are

1 provided to a control system; and the control system can provide independent feedback to each
2 of the second and third power sources so as to alter the speed of operation of those power sources
3 relative to one another (e.g., the second power source can be directed to speed up operation
4 and/or the third power source can be directed to slow down operation).

5 In yet another aspect, the present invention relates to a system for inspecting a substrate
6 in the form of a wrapping material for smoking article manufacture. The system is particularly
7 well suited for inspection of a web of paper wrapping material that has a discontinuous nature,
8 such as is provided by application of an additive material to all or a portion of that wrapping
9 material (e.g., as a pattern). The system possesses an emitter for directing radiation into contact
10 with the web of material containing a pattern such that the radiation impinges upon the web of
11 material and is absorbed. The system also possesses a detector (e.g., a near infrared sensor or
12 detector, or a non-contact ultrasonic transducer) for receiving reflected radiation from the web,
13 and for forming electrical signals representative of at least one selected component (e.g., water)
14 or representative change in mass of material corresponding to the presence of additive material.
15 The system further includes circuitry for processing the aforementioned electrical signals to
16 determine information relating to the presence of the pattern on the web, and for generating
17 output signals. The system further includes computing logic for receiving the output signals and
18 for determining whether those signals are representative of an unacceptable, irregular pattern on
19 the web or of an acceptable, desired pattern. The system further includes computer logic for
20 receiving information regarding irregular patterns and for signaling rejection of component
21 materials (e.g., formed cigarettes) manufactured from wrapping materials possessing additive
22 material that have been determined to possess irregular patterns.

23 Features of the foregoing aspects and embodiments of the present invention can be
24 accomplished singularly, or in combination, in one or more of the foregoing. As will be
25 appreciated by those of ordinary skill in the art, the present invention has wide utility in a
26 number of applications as illustrated by the variety of features and advantages discussed below.
27 As will be realized by those of skill in the art, many different embodiments of the foregoing are
28 possible. Additional uses, objects, advantages, and novel features of the present invention are set
29 forth in the detailed description that follows and will become more apparent to those skilled in
30 the art upon examination of the following or by practice of the invention.

BRIEF DESCRIPTION OF THE DRAWINGS

Figure 1 is a schematic illustration of a portion of a cigarette making machine showing a source of wrapping material, a source of tobacco filler and a garniture region that is used to produce a continuous cigarette rod.

Figure 2 is a schematic illustration of a cigarette making machine assembly including the combination of a wrapping material supply system and a cigarette making machine.

Figure 3 is a perspective of an additive applicator apparatus of one embodiment of the present invention, that additive applicator apparatus being mounted at an appropriate location on a cigarette making machine assembly.

Figure 4 is an exploded perspective of an additive applicator apparatus of the type shown in Figure 3.

Figure 5 is a schematic illustration of an additive applicator apparatus of one embodiment of the present invention.

Figure 6 is an exploded perspective of an additive applicator apparatus of the type shown in Figure 5.

Figure 7 is a schematic illustration of an additive applicator apparatus of one embodiment of the present invention.

Figure 8 is a schematic illustration of the outer side of the outer finger rail portion of a finger rail assembly.

Figure 9 is a schematic illustration of the outer side of the inner finger rail portion of a finger rail assembly.

Figure 10 is a schematic illustration of the outer side of the outer finger rail portion of a finger rail assembly.

Figure 11 is a schematic illustration of the outer side of the inner finger rail portion of a finger rail assembly.

Figure 12 is a perspective of a garniture entrance cone.

Figure 13 is an exploded perspective of a garniture entrance cone of the type shown in Figure 12.

Figure 14 is an enlarged schematic cross-sectional view of a pair of finger rails and a garniture entrance cone, as taken along lines 14 in Figure 1.

1 Figure 15 is a block diagram showing the components and general operation of a
2 registration system and an inspection system.

3 Figures 16-19 are schematic representations of various timing signals associated with
4 registration and inspection systems.

5 Figure 20 is a schematic illustration of a side view of an apparatus for making a smoking
6 article and wrapper, and specifically, a schematic illustration of a portion of a cigarette making
7 machine showing a source of wrapping material, an additive applicator apparatus, a source of
8 tobacco filler and a garniture region that is used to produce a continuous cigarette rod.

10 of the present invention.

11 Figure 22 is a schematic illustration of an additive applicator apparatus of an embodiment
12 of the present invention.

13 Figure 23 is a perspective of an additive applicator apparatus of one embodiment of the
14 present invention, that additive applicator apparatus being mounted at an appropriate location on
15 a cigarette making machine assembly.

16 Figures 24 - 28 are perspectives of a portion of an additive applicator apparatus of the
17 type shown in Figure 23.

19 **DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS**

20 Aspects and embodiments of the present invention include cigarette making machines
21 and components thereof that are useful for manufacturing cigarettes, and in particular, that are
22 useful for transferring and retaining additive material on a paper wrapping web in an efficient,
23 effective and desired manner. Figures 1- 28 illustrate those aspects and embodiments. Like
24 components are given like numeric designations throughout the figures.

25 A conventional automated cigarette rod making machine useful in carrying out the
26 present invention is of the type commercially available from Molins PLC or Hauni-Werke
27 Korber & Co. KG. For example, cigarette rod making machines of the type known as Mk8
28 (commercially available from Molins PLC) or PROTOS (commercially available from Hauni-
29 Werke Korber & Co. KG) can be employed, and can be suitably modified in accordance with the
30 present invention. A description of a PROTOS cigarette making machine is provided in U.S.
31 Patent No. 4,474,190 to Brand, at col. 5, line 48 through col. 8, line 3, which is incorporated

1 herein by reference. Types of equipment suitable for the manufacture of cigarettes also are set
2 forth in U.S. Patent Nos. 4,844,100 to Holznagel; 5,156,169 to Holmes et al. and 5,191,906 to
3 Myracle, Jr. et al.; U.S. Patent Application 2003/0145866 to Hartman; U.S. Patent Application
4 2003/0145869 to Kitao et al.; U.S. Patent Application 2003/0150466 to Kitao et al.; and PCT
5 WO 02/19848. Designs of various components of cigarette making machines, and the various
6 material used to manufacture those components, will be readily apparent to those skilled in the
7 art of cigarette making machinery design and operation.

8 Referring to Figure 1, a one-component cigarette making machine assembly 8 includes
9 cigarette making machine 10. The cigarette making machine 10 includes a chimney region 16
10 that provides a source of tobacco filler 20, or other smoking material. The tobacco filler 20 is
11 provided continuously within an upwardly moving air stream (shown by arrow 22), and is blown
12 onto the lower outside surface of a continuous conveyor system 28. The conveyor system 28
13 includes an endless, porous, formable conveyor belt 32 that is supported and driven at each end
14 by left roller 36 and right roller 38. A low pressure region or suction chamber 41 within the
15 foraminous belt 32 acts to attract and retain tobacco filler 20 against the bottom of the conveyor
16 system 28. As such, tobacco filler 20 located below the conveyor belt 32 is pulled upward
17 toward that belt, thereby forming the tobacco filler into a tobacco stream or cake on the lower
18 surface of that belt. The conveyor belt 32 thus conveys the stream of tobacco filler 20 to the left;
19 toward a garniture section 45 of the cigarette making machine 10. An ecreteur or trimmer disc
20 assembly 48 assists in providing transfer of the appropriate amount of tobacco filler 20 to the
21 garniture region 45. Descriptions of the components and operation of several types of chimneys,
22 tobacco filler supply equipment and suction conveyor systems are set forth in U.S. Patent Nos.
23 3,288,147 to Molins et al.; 4,574,816 to Rudszinat; 4,736,754 to Heitmann et al. 4,878,506 to
24 Pinck et al.; 5,060,665 to Heitmann; 5,012,823 to Keritsis et al. and 6,630,751 to Fagg et al.; and
25 U.S. Patent Application 2003/0136419 to Muller.

26 Meanwhile, a continuous web of paper wrapping material 55 is supplied from a bobbin
27 58. The bobbin is supported and rotated using an unwind spindle assembly 59.

28 The paper web 55 is routed on a desired path using a series of idler rollers and guideposts
29 (shown as rollers 60, 61), through an optional printing assembly device 65, and ultimately
30 through the garniture region 45. Typically, product indicia are printed onto the paper web 55 at
31 predetermined regions thereof using printing assembly 65. Printing assemblies for printing

1 product indicia (e.g., logos in gold colored print) are component parts of commercially available
2 machines, and the selection and operation thereof will be readily apparent to those skilled in the
3 art of cigarette making machine design and operation. Techniques for registering the location of
4 printed product indicia on the ultimate cigarette product (e.g., on the paper wrapper of a cigarette
5 rod in a location immediately adjacent to the tipping material of that product) are known to those
6 skilled in the art of automated cigarette manufacture.

7 The paper web 55 also is routed through an applicator system 70 prior to the time that the
8 web reaches the garniture section 45. The applicator system 70 is employed to apply a desired
9 pattern of additive material 73 to the paper web 55. A representative pattern is provided by
10 applying spaced bands that are aligned transversely to the longitudinal axis of the paper web 55.
11 A representative additive material 73 is a coating formulation in a liquid, syrup or paste form.

12 Optionally, though not preferably, the paper web 55 can be routed through a
13 heating/cooling control unit (not shown) immediately before the paper web passes through the
14 applicator system 70. A suitable heating/cooling unit is a heating unit having the form of an
15 infrared heater (not shown), and that heater can be operated at any desired temperature; for
16 example, at a temperature of about 180°C to about 220°C. The heating/cooling unit can be used
17 to provide the paper web 55 at a desired temperature (e.g., the paper web can be pre-heated)
18 immediately prior to application of the additive material formulation 73 to the surface of that
19 paper web.

20 A representative additive applicator 70 comprises a pick-up roller 78 and a transfer roller
21 82. The pick-up roller 78 includes a plurality of patterned (e.g., evenly spaced apart) pockets on
22 its roll face (not shown) into which a predetermined amount of additive is deposited. The
23 positioning, shape and number of pockets can vary, and typically depends upon the pattern that is
24 desired to be applied to the paper web 55 (e.g., spaced apart pockets can be used to place spaced
25 bands of additive material 73 on the web). For example, in one embodiment of a transfer roller
26 82, seven pockets each having the form of transversely aligned bands each placed about 46 mm
27 apart. The shape, including depth, of each pocket can determine the amount of additive material
28 that can be carried by that pocket, and hence applied to the paper web 55.

29 The additive material 73 typically is provided from a supply source reservoir (not shown)
30 through tubing or other suitable supply means (not shown) to a port or supply region 85 near the

1 head (i.e., infeed region) of the pick-up roller 78. The additive material 73 is fed from the head
2 of the pick-up roller into the pockets of the pick-up roller.

3 If desired, the supply region and the region of the pick-up roller 78, and other relevant
4 regions of the additive applicator 70, can be supplied with heat control system using a suitable
5 heating or cooling device (not shown). As such, a heating device can provide a heated region
6 that can be used to assist in maintaining a solid or very viscous coating formulation in a melted
7 form, such as in the form of a liquid, syrup or paste. A representative heating device is an
8 electrical resistance heating unit controlled by a rheostat; and the heating device can be
9 appropriately fashioned so as to transfer the desired amount of heat to the various components of
10 the additive applicator 70. As such, sufficient heat can be provided to provide coating
11 formulation at a temperature above ambient temperature, and for example, at a temperature
12 within the range of about 120°F to about 180°F. If desired, heat insulation material (not shown)
13 can be positioned in adjacent regions of the cigarette making machine 10 in order that transfer of
14 heat to other regions of that machine is minimized or prevented.

15 Operation of the pick-up roller 78 and the transfer roller 82 are timed and controlled
16 relative to the speed of operation of the cigarette making machine 10. As the pick-up roller 78
17 and the transfer roller 82 are engaged in roll contact, and rotate in contact with each other on
18 their respective peripheral surfaces in a controlled manner, the additive material 73 is transferred
19 from the pockets of the pick-up roller 78 onto predetermined regions of the roll face surface (not
20 shown) of the transfer roller 82. The additive material 73 is transferred onto the transfer roller 82
21 surface in essentially the same pattern as that of the spaced apart pockets on the pick-up roller 78
22 (i.e., the pattern applied to the paper web is dictated by the design of the pattern of the roll face
23 of the pick-up roller 78).

24 The paper web 55 comprises two major surfaces, an inside surface 88 and an outside
25 surface 90. The stream of tobacco filler 20 ultimately is deposited upon the inside surface 88 of
26 the paper web 55, and the additive material 73 most preferably also is applied to the inside
27 surface 88 of that web. As the paper web 55 travels across the surface of the rotating transfer
28 roller 82, the additive material 73 on the surface of the transfer roller 82 is transferred to the
29 inside surface 88 of the advancing paper web 55 at locations corresponding to the location of the
30 pockets located on the roll face of the pick-up roller 78.

1 After the additive material 73 has been applied to the paper web 55, the web can be
2 exposed to a sensor or detector 95 for a measurement system, such as a registration system
3 and/or an inspection system (not shown). Preferably, the detector 95 is mounted on the frame of
4 the cigarette making machine 10 and is positioned so as to receive information concerning the
5 paper web 55 immediately after additive material 73 has been applied to that paper web.
6 Typically, the detector 95 is a component of certain registration systems and inspection systems
7 of the present invention. Suitable detector systems are described hereinafter in greater detail
8 with reference to Figure 15. Alternative sensors, detectors and inspection system components
9 and description of inspection system technologies and methods of operation are set forth in U.S.
10 Patent Nos. 4,845,374 to White et al.; 5,966,218 to Bokelman et al.; 6,020,969 to Struckhoff et
11 al. and 6,198,537 to Bokelman et al. and U.S. Patent Application 2003/0145869 to Kitao et al.;
12 U.S. Patent Application 2003/0150466 to Kitao et al.; which are incorporated herein by
13 reference.

14 A representative inspection system employs a capacitance detector positioned
15 downstream from the applicator system 70. A preferred detector is a non-contact detector that
16 can sense changes in the dielectric field of the paper web resulting from the application of
17 additive material to certain regions of that paper web. A representative detector is a Hauni Loose
18 End Detector, Part Number 2942925CD001500000 that is available from Hauni-Werke Korber
19 & Co. KG. The detector is combined with appropriate electronics for signal processing. That is,
20 the detector generates an electrical signal, and appropriate electronic circuitry is used to compare
21 that signal relative to a programmed threshold level. Such a signal allows for graphical display
22 of the profile of applied additive material along the length of the paper web. When application
23 of a band of additive material does not occur as desired (i.e., a band is missing on the paper web,
24 or the amount of additive material that is applied is not the desired amount) a signal is generated.
25 As such, rejection of poor quality rods, and adjustments to the overall operation of the cigarette
26 making machine, can occur. In addition, an output signal from such a measurement system can
27 be used in a feedback control system to maintain the desired level of additive material to the
28 paper web and/or to maintain the desired rate of feed of coating formulation to the applicator
29 system.

30 Additionally, after the additive material 73 has been applied to the paper web 55, the web
31 can be passed through an optional heating/cooling control device 120. The control device 120

1 can be used to alter the heat to which the paper web 55 and additive material 73 is subjected
2 (e.g., by raising or lowering temperature). For example, the heating/cooling control device can
3 be a heating or drying device adapted to assist in the removal of solvent (e.g., moisture) from the
4 additive material 73 that has been applied to the paper web 55. Alternatively, for example, the
5 heating/cooling control device can be a cooling device adapted to assist in the hardening melted
6 additive material 73 that has been applied to the paper web 55 using a heated additive applicator
7 system 70. Typically, the heating/cooling control device 120 has a tunnel-type configuration
8 through which the paper web 55 is passed; and during the time that the paper web is present
9 within that tunnel region, the paper web is subjected to heating supplied by a convection or
10 radiant heating device, or cooling supplied by a refrigerant-type, solid carbon dioxide-type or
11 liquid nitrogen-type cooling device.

12 Typically, the region of the cigarette making machine 10 where the heating/cooling
13 device 120 is located does not afford sufficient room to provide a heating/cooling control device
14 120 of any appreciable size. For this reason, it is desirable to locate such an optional
15 heating/cooling device 120 in a location that is offset from the cigarette making machine. For
16 example, appropriately located and positioned turning bars (not shown) can be used to direct the
17 paper web 55 outward (and optionally upward or downward) from the front face of the cigarette
18 making machine 10, and the paper web 55 can be routed through the heating/cooling device 120
19 that can be supported but frame or other suitable support means (not shown), and appropriately
20 located and positioned turning bars (not shown) can be used to direct the paper web 55 so
21 subjected to heating or cooling back to the cigarette making machine 10 for continued use in the
22 cigarette manufacturing process.

23 Optionally, though not preferably, the indicia printing assembly 65 can be modified in
24 order to print formulations other than printing inks and intended for purposes other than product
25 indicia. For example, the printing assembly 65 can be adapted to apply coating formulations
26 having intended purposes other than product indicia. For example, fluid coating formulations
27 (e.g., that incorporate pre-polymer components and are essentially absent of solvent, or that are
28 water-based), can be applied to either the inside surface or outside surface of the paper web 55,
29 using a suitably adapted printing assembly 65. Such coating formulations can be supplied using
30 a pump or other suitable means (not shown) from a reservoir (not shown) through a tube or other
31 suitable supply means (not shown). The paper web 55 having water-based additive material (not

1 shown) applied thereto is subjected to exposure to heat or microwave radiation using heat source
2 126, in order to dry the coating formulation and fix additive material to the desired location on
3 the paper web. A reflective shield or cover (not shown) can be positioned over that radiation
4 source 126. The previously described heating/cooling control device 120 and/or the radiation
5 source 122 also can be employed.

6 The paper web 55 travels toward the garniture region 45 of the cigarette making machine
7 10. The garniture region 45 includes an endless formable garniture conveyor belt 130. That
8 garniture conveyor belt 130 conveys the paper web 55 around a roller 132, underneath a finger
9 rail assembly 140, and advances that paper web over and through a garniture entrance cone 144.
10 The entrance cone 144 also extends beyond (e.g., downstream from) the finger rail assembly
11 140. The right end of the garniture conveyor belt 130 is positioned adjacent to and beneath the
12 left end of the suction conveyor system 28, in order that the stream of tobacco filler 20 carried by
13 conveyor belt 32 is deposited on the paper web 55 in that region. The finger rail assembly 140
14 and garniture entrance cone 144 combine to provide a way to guide movement of an advancing
15 tobacco filler cake 20 from the suction conveyor 32 to the garniture region 45. Selection and use
16 of finger rail assemblies and garniture entrance cones will be readily apparent to those skilled in
17 the art of cigarette manufacture. Alternatively, finger rail assemblies and/or garniture entrance
18 cones that are described in greater detail hereinafter with reference to Figures 8-14 can be
19 employed.

20 As the conveyor belt 32 and tobacco filler cake 20 travel within the finger rail assembly
21 140, vacuum suction applied to the inside region of the conveyor belt 32 is released. As a result,
22 tobacco filler 20 is released from contact with the conveyor belt 32, falls downwardly from that
23 conveyor belt through a longitudinally extending track (not shown) within the finger rail
24 assembly 140, and is deposited onto the advancing paper web 55 at the left side of the garniture
25 region 45 immediately below the finger rail assembly. In conjunction with the release of vacuum
26 from the conveyor belt 32, removal of tobacco filler 20 from the conveyor belt 32 and deposit of
27 that tobacco filler onto the moving paper web 55 is facilitated through the use of a shoe or scrape
28 155 or other suitable means, that is used to peel or otherwise physically remove advancing
29 tobacco filler 20 off of the outer surface of the extreme left end of the conveyor belt 32.

30 The garniture section 45 includes a tongue 160 adjacent to the distal end of the finger rail
31 assembly 140 and above the top surface of the garniture conveyor belt 130. The tongue 160

1 provides a commencement of constriction of the tobacco filler 20 that has been deposited on the
2 paper web 55. Meanwhile, the garniture conveyor belt 130 begins to form that tobacco filler
3 stream and paper web 55 into a continuous rod 170. The tongue 160 extends to a point where the
4 paper web 55 is secured around that stream of tobacco filler. The tongue 160 and the garniture
5 conveyor belt 130 define a passage which progressively decreases in cross-section in the
6 direction of movement of the tobacco filler stream, such that the deposited tobacco filler stream
7 progressively forms a substantially circular cross-section that is desired for the ultimate finished
8 continuous cigarette rod 170.

9 The garniture section 45 also includes a folding mechanism 180 on each side of the
10 garniture conveyor belt 130 located adjacent to, and downstream from, the tongue 160. The
11 folding mechanism 180 is aligned in the direction of filler stream movement, further compresses
12 the tobacco filler 20 within the rod that is being formed, and folds the paper web 55 around the
13 advancing components of the forming continuous cigarette rod 170. A fashioned continuous
14 tobacco rod that exits the tongue 160 and folding mechanism 180 then passes through an
15 adhesive applicator 184, in order that adhesive is applied to the exposed length or lap seam
16 region of the paper web 55. That is, the exposed length of paper web 55 then is lapped onto
17 itself, and the adhesive is set that region in order to secure the paper web around the tobacco
18 filler 20, thereby forming the continuous cigarette rod 170. The continuous rod 170 passes
19 through a cutting or subdivision mechanism 186 and this subdivided into a plurality of rods 190,
20 191 each of the desired length. The selection and operation of suitable subdivision mechanisms
21 186, and the components thereof, will be readily apparent to those skilled in the art of cigarette
22 manufacture. For example, the cutting speed of knife (not shown) within a ledger or other
23 suitable guide 192 is controlled to correspond to the speed that the cigarette making machine 10
24 is operated. That is, the location that an angled flying knife (not shown) cuts the continuous rod
25 170 into a plurality of rods 190, 191, each of essentially equal length, is controlled by controlling
26 the speed of operation of that knife relative to speed that the cigarette making machine supplies
27 the continuous rod.

28 Typically, operation of the conveyor belt 32, garniture belt 130 and flying knife (not
29 shown) within ledger 192 all are mechanically linked to one another by belts or other suitable
30 means, and are driven off of the same power source (not shown). For example, for a cigarette
31 making machine, such as a PROTOS 80 that is commercially available from Hauni-Werke

1 Korber & Co. KG, the main motor of that cigarette making machine is used to drive operation of
2 the conveyor belt 32, the garniture belt 130 and the flying knife. An alternate design of such a
3 type of cigarette making machine can be provided by providing power to the flying knife from
4 one power source, such as the motor of a servo system (not shown); and the power to the
5 garniture belt 130 and the conveyor belt 32 can be provided from a second power source, such as
6 the motor of a second servo system (not shown). Typically, power for operation of the garniture
7 belt 130 is provided by suitable mechanical connection to the second power source, and the
8 power for operation of the conveyor belt 32 is provided by suitable linkage to the operation of
9 the garniture belt by suitably adapted timing belt systems, or other suitable means (not shown).
10 Encoders (not shown) mechanically coupled to the first and second servo systems (not shown)
11 provide information to a processing unit (not shown) regarding cigarette manufacturing speed,
12 and garniture speed, respectively. The detector 95 (e.g., such as a non contact ultrasonic
13 detector) also can be adapted to provide information regarding location of additive material 73
14 that has been applied to the paper web 55 to the same processing unit (not shown). Using the
15 processing unit, the positioning of applied pattern on the paper web 55 can be compared to a
16 specified positioning of the pattern, and the processing unit can be used to alter the speed of
17 operation of the two servo systems relative to one another to bring cigarette rods 190, 191 that
18 are out of specification back to within specification. For example, the speed of operation of the
19 flying knife can be increased and/or the speed of operation of the garniture belt can be decreased
20 until cigarette rods are determined to be back within the desired range of tolerance or within
21 specification.

22 Servo control systems and the operation thereof will be readily apparent to those skilled
23 in the art of cigarette making machine design and operation. Representative servo systems are
24 readily available as Single Axis Controller P/N: DKC03.3-040-7FW/FWA-EDODR3-FGP-
25 04VRS-MS, Motor P/N: MKD025-144-KP1-KN SERVO MOTOR from Indramat; Ultra 5000
26 Single Axis P/N: 2098-IPD-010 Motor P/N: Y-2012-1-H00AA from Allen Bradly; and Servo
27 P/N :SC752A-001-01 Motor P/N: R34-GENA-HS-NG-NV-00 from Pacific Scientific.

28 Information concerning the position and speed of operation of the flying knife can be fed
29 to a servo control system that incorporates a multi-axes programming unit. Such a servo system
30 is available as PPC-R02-2N-N-N1-V2-NN-FW from Indramat. As such, the servo system can be
31 used to observe and control the transfer roller to a known position relative to the flying knife.

1 Preferred cigarette making machines, such as PROTOS machines, can possess an automatic
2 servo-driven print displacement control systems as well as servo-driven paper tension control
3 systems. Thus, the distance of travel of the paper web between the applicator system and the
4 continuous cigarette rod cutoff knife can be changed; for example, when adjustments are made to
5 correct for print displacement relative to the cut in the continuous rod or to control paper tension
6 to avoid paper breakage. Such changes in distance of travel of the paper web can vary; and for
7 example, the changes of as much as 35 mm in paper travel can be provided for adjustments for
8 print displacement, and changes of as much as 20 mm in paper travel can be provided for paper
9 tension adjustments. Thus, when any adjustments are made that result in a change in the length
10 of the path of travel of the paper web from the applicator roller to the flying knife, the multi-axes
11 control system can be used to make the corresponding adjustments to the speed of operation of
12 the applicator roller. Most preferably, adjustments to the speed of operation of the applicator
13 roller are provided at times when the applicator roller is not in the process of applying additive
14 material to the paper web. As such, adjustments programmed to occur between the application
15 of successive bands result in avoiding smearing of additive material on the paper web and in
16 avoiding paper breakage. To minimize the number of reject cigarettes, adjustments can be made
17 on a single rod resulting in only a single rejected rod, or adjustments can be made as small
18 changes spread out over a number of cigarette rods until the application system is adjusted to be
19 back to providing cigarettes having patterns applied at the desired locations.

20 Those cigarette rods 190, 191 then most preferably have filter elements (not shown)
21 attached thereto, using known components, techniques and equipment (not shown). For
22 example, the cigarette making machine 10 can be suitably coupled to filter tipping machine (not
23 shown), such as a machine available as a MAX, MAX S or MAX 80 Hauni-Werke Korber & Co.
24 KG. See, also, for example, U.S. Patent Nos. 3,308,600 to Erdmann et al. and 4,280,187 to
25 Reuland et al.

26 The cigarette making machine assembly and configuration described with reference to
27 Figure 1 are representative of a single cigarette making machine that provides both the tobacco
28 filler and the patterned paper web to the garniture region of that machine. Cigarette making
29 machine assemblies and configurations representative of those that provide the tobacco filler to
30 the garniture region from one location, and the patterned paper web to the garniture region from
31 another location, (i.e., multi-component systems), are described with reference to Figure 2.

Referring to Figure 2, there is shown a two-component automated cigarette making machine assembly 8 that is constructed by coupling a wrapping material supply machine 200 (e.g., a first component) with a cigarette making machine 10 (e.g., a second component).

A suitable wrapping material supply machine 200 can be provided by appropriately modifying a web supply unit available as SE 80 from Hauni-Werke Korber & Co. KG. See, for example, U.S. Patent No. 5,156,169 to Holmes et al., which is incorporated herein by reference. Other suitable unwind units, such those having the types of components set forth in U.S. Patent No. 5,966,218 to Bokelman et al., also can be employed. The supply machine 200 most preferably is a free-standing machine that is capable of providing a patterned web of wrapping material 55 to a conventional (or suitably modified) cigarette making machine 10. The supply machine 200 includes a frame 205 that supports at least one unwind spindle assembly 220 onto which a first bobbin 224 is mounted. Preferably, the supply machine 200 includes a second unwind spindle assembly 228 for a second bobbin (not shown), and a web splicing mechanism 232.

The paper web 55 is threaded through a tension sensor 236, which, in conjunction with a braking component 239 is connected to the shaft of the unwind spindle assembly, maintains a desired amount of tension on the paper web 55 as it is transferred from the bobbin 224.

In operation, a continuous paper web 55 supplied from a bobbin 58 is routed through a path defined by a series of idler rollers 245, 247 and guideposts 255, 256. The paper web 55 also is routed through an applicator system 70 that is used to apply a desired pattern of additive material 73 to the paper web 55. A representative additive material 73 is a coating formulation in a liquid, syrup or paste form. Optionally, though not preferred, the paper web can be routed through a heating/cooling control unit (not shown) immediately before the paper web passes through the applicator system 70.

A representative additive applicator 70 comprises a pick-up roller 78 and a transfer roller 82, and can be operated in essentially the same manner as described previously with reference to Figure 1. The additive material 73 typically is provided from a supply source reservoir (not shown) through tubing (e.g., Tygon-type or polyethylene tubing) or other suitable supply means (not shown) to a port or supply region 85 near the head (i.e., infeed region) of the pick-up roller 78. If desired the supply region and the region of the pick-up roller can be supplied with heat using a suitable heating device (not shown). The additive material 73 is fed from the head of the

1 pick-up roller into the pockets of the pick-up roller. As the pick-up roller 78 and the transfer
2 roller 82 are engaged in roll contact, and rotate in contact with each other, the additive material
3 73 is transferred from the pockets of the pick-up roller 78 onto predetermined regions of the roll
4 face surface (not shown) of the transfer roller 82. The additive material 73 is transferred onto the
5 transfer roller 82 surface in essentially the same pattern as that of the spaced apart pockets on the
6 pick-up roller 78 (i.e., the pattern on the paper web is defined by that pattern on the roll face of
7 the pick-up roller). The additive material 73 most preferably also is applied to predetermined
8 locations on the inside surface 88 of the paper web 55.

9 After the additive material 73 has been applied to the paper web 55, the web can be
10 exposed to a sensor or detector 95 for a registration system and/or an inspection system (not
11 shown). Preferably, the detector 95 is positioned so as to receive information concerning the
12 paper web 55 immediately after additive material 73 has been applied to that paper web.
13 Typically, the detector 95 is used in conjunction with the certain registration systems and
14 inspection systems of the present invention. Suitable detector systems are described hereinafter
15 in greater detail with reference to Figure 15. Alternative sensors, detectors and inspection
16 system components and description of inspection system technologies and operation are set forth
17 in U.S. Patent Nos. 4,845,374 to White et al.; 5,966,218 to Bokelman et al.; 6,020,969 to
18 Struckhoff et al. and 6,198,537 to Bokelman et al.; which are incorporated herein by reference.

19 Additionally, after the additive material 73 has been applied to the paper web 55 (i.e.,
20 downstream from the applicator apparatus 70), the web can be passed through an optional,
21 though highly preferred, heating/cooling control device 280, or other suitable means for
22 controlling heat to which the paper web is subjected. The control device 280 can be used to alter
23 the heat to which the paper web 55 and additive material is subjected (e.g., by raising or lowering
24 the temperature). For example, the control device can be a heating or drying device adapted to
25 assist in the removal of solvent (e.g., moisture) from the additive material 73 that has been
26 applied to the paper web 55. Alternatively, for example, the heating/cooling control device can
27 be a cooling device adapted to assist in the hardening melted additive material 73 that has been
28 applied to the paper web 55 using a heated additive applicator system 70. Typically, the
29 heating/cooling control device 280 has a tunnel-type configuration through which the paper web
30 55 is passed (through an inlet end 282 and out an outlet end 283); and during the time that the
31 paper web is present within that tunnel region, the paper web is subjected to heating supplied

1 using infrared convection or radiant heating devices, or cooling supplied using refrigerant-type,
2 solid carbon dioxide-type or liquid nitrogen-type cooling devices.

3 The size of the heating/cooling device 280 can vary, particularly because that device is
4 positioned and supported by a component 200 that is physically separated from, and spaced
5 from, the cigarette making machine 10. That is, there is provided sufficient room to subject the
6 paper web 55 to treatment using the heating/cooling device 280. Exemplary heating/cooling
7 devices 280 have lengths of about 2 feet to about 10 feet, with lengths of about 3 feet to about 8
8 feet being typical, and lengths of about 4 feet to about 7 feet being desirable. The distance that
9 the paper web 55 travels through the heating/cooling device 280 (i.e., the length of travel through
10 that device) can vary. For example, the paper web 55 can be routed back and forth within the
11 heating/cooling device 280 using a suitably adapted roller system configuration (not shown).

12 Most preferably, the heating/cooling control device 280 is used to provide radiant heating
13 to the paper web 55. An exemplary heating and drying system 280 is available as IMS Model
14 No. P24N002KA02 2kW, 2450 MHz Linear Drying System from Industrial Microwave Systems,
15 Inc. Representative types of radiant drying systems are set forth in U.S. Patent Nos. 5,958,275 to
16 Joines et al.; 5,998,774 to Joines et al.; 6,075,232 to Joines et al.; 6,087,642 to Joines et al.;
17 6,246,037 to Drozd et al. and 6,259,077 to Drozd et al.; all of which are incorporated herein by
18 reference. Such types of radiant drying systems can be manufactured from materials such
19 aluminum and aluminum alloys. See, also, U.S. Patent No. 5,563,644 to Isganitis et al., which is
20 incorporated herein by reference.

21 Radiant-type drying systems are preferred, because typical infrared-type drying systems
22 require relatively long residence times to adequately remove effective quantities of solvent or
23 liquid carrier (e.g., water) from the paper web 55. For fast moving paper webs 55 running at
24 nominal cigarette making machine speeds, the application of sufficient heat demands the need
25 for relatively long infrared-type drying apparatus. Additionally, sufficient heat from infrared-
26 type drying systems requires the use of relatively high temperatures; thus providing the
27 propensity for scorching and browning of certain areas of the paper web, and the risk of fire. For
28 example, for a conventional cigarette making machine operating so as to produce about 8,000
29 cigarette rods per minute, and having bands of additive material applied to the advancing paper
30 web so that about 1 mg of water is applied to each individual cigarette rod, about 350 to about
31 700 watts per hour is effectively required to remove that water from the paper web.

1 A microwave-type drying system is desirable because effectively high amounts of heat
2 can be employed in controlled manners. An exemplary system is one that employs planar wave
3 guide of about 36 inches in length, an internal width of about 1.6 inches, and an internal depth of
4 about 3.7 inches. Preferred wave guides are of dimension to allow passage of only lowest order
5 (i.e., TE₁₀) or single mode radiation. An exemplary system also can possess inlet and outlet ends
6 282, 283 that both have widths of about 1.75 inch and heights of about 0.37 inch. Within the
7 inner region of the drying system, immediately within each end of the inlet and outlet ends 282,
8 283, are positioned choke flanges, pin chokes (not shown) or other means to assist in the
9 prevention of escape or leakage of radiation from the system; and those flanges or pins typically
10 extend about 3 inches into the system from each respective end.

11 Microwave-type drying systems can apply heat to desirable locations on the paper web
12 55 where heat is needed (i.e., in the printed regions of the paper web). In one preferred radiant-
13 type drying system, microwave energy is launched at one end of a waveguide and is reflected at
14 the other end of that waveguide, resulting in the paper web experiencing radiant energy for
15 effectively an extended period. Precise drying control can be achieved by attenuating the
16 microwave energy and/or the path of the paper web within the microwave drying system. Such
17 radiant-type drying systems thus can be used to evaporate the solvent or liquid carrier (e.g.,
18 water) of the additive material formulations by applying the microwave energy uniformly
19 throughout the patterned region (e.g., to the bands of applied additive material coating
20 formulation).

21 The controls for the radiant-type dryer (e.g., the microwave control and associated safety
22 systems) most preferably are integrated into the programmable logic controller-based (PLC-
23 based) control system (not shown) for supervisory control. The PLC-based system (not shown)
24 enables radiant energy production, and disables the radiant energy production when radiant
25 energy is not needed for drying (e.g., such as when the production system is stopped or paper
26 web experiences a break). The top and bottom regions of the wave guide of the drying system in
27 portions of the drying region can be perforated with a plurality of perforations (not shown) to
28 allow for the removal of moisture, without allowing radiation (e.g., microwave radiation) from
29 escaping into the surroundings. A suitably designed shroud 287 and an electrically driven fan
30 (not shown) can be placed over the top of those perforations in order to remove the evaporated
31 moisture away from the paper web and remove dust from the system. If desired, the fan (not

1 shown) also can be under the control of the PLC-based system, and as such, only operate during
2 operation of the cigarette manufacturing system 8.

3 For a radiant heating system 280 for the embodiment shown in Figure 2, radiant
4 microwave energy is supplied by a generator 290 for electromagnetic radiation, which is located
5 one end of that system. Typically, higher power generators are used to produce heat to remove
6 greater amounts of moisture; and generators producing up to about 10 kW of power, and usually
7 up to about 6 kW of power, are suitable for most applications. Radiation produced by the
8 generator is passed through appropriate wave guides and circulators (not shown). The
9 microwave radiation passes through a curved wave guide 292 and through a drying region 294
10 for the paper web 55. A typical drying region for a microwave drying system has a length of
11 about 30 inches. As such, the radiation supplied to the drying system and the paper web 55
12 move in the same overall direction through that drying system. Radiation that travels through the
13 drying region 294 is reflected by suitable reflector 296 (i.e., a short plate or reflector plate) at the
14 other end of the drying system. That radiation is reflected back through the drying region, back
15 through the channel at the other end of the heating system, and as such, the reflected radiation
16 and the paper web 55 move in an overall counter current manner relative to one another. Any
17 remaining radiation is appropriately redirected through appropriately positioned wave guides and
18 circulators to a dry air-cooled load 298, or other suitable radiation dissipation means. As such,
19 the radiation is converted to heat, and the resulting heat can be removed using electrical fans (not
20 shown) or other suitable means.

21 In a preferred embodiment (not shown), the positioning of the heating device 280 shown
22 in Figure 2 is reversed (e.g., the heating device is rotated 180°) such that the paper web 55 enters
23 at the end of the heating device possessing the reflector 296 and exits at the end through which
24 radiation enters the channel 292 from the generator 290. As such, radiation entering the drying
25 system from the source of radiation and the paper web 55 travel in an overall counter current
26 manner relative to one another.

27 The additive applicator 70 used in conjunction with the supply machine 200 most
28 preferably is driven by a servo drive control system (not shown) or other suitable control means.
29 Suitable servo-based systems and the operation thereof are described in greater detail hereinafter
30 with reference to Figure 15. As such, the positioning of the additive material on the paper web
31 55 can be controlled relative to the location that the continuous cigarette rod 170 that is

1 manufactured using the second component 10 is cut into predetermined lengths, and hence,
2 registration of the applied pattern of additive material on a finished cigarette can be achieved.
3 That is, the automated cutting knife (not shown) for subdividing the continuous rod into
4 predetermined lengths can be controlled relative to those components used to apply additive
5 material to the paper web that is used to provide that continuous rod.

6 The paper web 55 exits the temperature control device 280 and is advanced to the
7 cigarette making machine 10. Direction of the paper web 55 is provided by suitably aligned
8 series of idler rollers 312, 314, 316 (or guideposts, turning bars, or other suitable means for
9 directing the paper web from the first component 200 to the second component 10). Suitable
10 pathways for travel of the paper web 55 can be provided by suitably designed tracks or tunnels
11 (not shown). As such, there is provided a way to direct the paper web from the first component
12 200 to the second component 10.

13 The continuous paper web 55 is received from the first component 200 by the second
14 component 10. Typically, the paper web 55 is directed from idler roller 316 to roller 60 of the
15 cigarette making machine 10, or other suitable location. The paper web 55 travels through
16 printing assembly 65 where indicia can be printed on the outer surface 90 of that web, if desired.
17 The paper web 55 then travels to the garniture region 45 of the cigarette making machine 10,
18 where there are provided components for manufacturing a continuous cigarette rod 170 by
19 wrapping the tobacco filler 20 in the paper web. The garniture conveyor belt 130 advances that
20 paper web through that garniture region. At the left end of the suction conveyor system 28,
21 tobacco filler 20 is deposited from its source on the foraminous belt 32 onto the paper web 55.
22 The garniture region 45 includes finger rail assembly 140, garniture entrance cone 144, scrape
23 155, tongue 160, folding mechanism 180 and adhesive applicator 184, that are employed to
24 provide a continuous cigarette rod 170. The continuous rod 170 is subdivided into a plurality of
25 rods (not shown), each of the desired length, using known techniques and equipment (not
26 shown). Those rods then most preferably have filter elements attached thereto, using known
27 techniques and equipment (not shown).

28 The cigarette making machine assembly and configuration described with reference to
29 Figure 2 are representative of cigarette making machine assemblies and configurations that can
30 be used to provide tobacco filler 20 to a garniture region 45 from one location, and the patterned
31 paper web 55 to the garniture region from another location. Furthermore, the representative

1 cigarette making machine assembly (i.e., with the component that provides the patterned paper
2 web positioned to the front and to the right of the component that incorporates the tobacco source
3 and the garniture assembly) is such that the general direction of travel of the paper web through
4 the wrapping material supply machine is essentially parallel to the direction of travel of the paper
5 web through the garniture region of the cigarette making machine. However, the positioning of
6 the wrapping material supply machine to the cigarette making machine can vary. For example,
7 the wrapping material supply machine 200 can be positioned beside or behind the cigarette
8 making machine; or positioned generally perpendicular to the garniture region of the cigarette
9 making machine 10. In such circumstances, the path of travel of the paper web from the
10 wrapping material supply machine to the cigarette making machine can be accomplished through
11 the use of appropriately positioned idler bars and roller guides. The exact path of travel of the
12 paper web is a matter of design choice, and the selection thereof will be readily apparent to those
13 skilled in the art of design and operation of cigarette manufacturing equipment.

14 Referring to Figure 3, there is shown a portion of a cigarette making machine assembly 8
15 of the present invention. In particular, there is shown an additive applicator apparatus 70
16 representative of one aspect of the present invention. Such an additive applicator 70 is
17 particularly useful for applying to a paper web 55 additive materials that are not particularly
18 viscous (e.g., formulations of additive materials having viscosities of less than about 1,000
19 centipoise).

20 Additive applicator 70 is an assembly that includes a pick-up roller 78 and a transfer
21 roller 82 mounted adjacent to each other and through a first or front roller support plate 400 on
22 the exterior front face of the cigarette making machine assembly 8. A second or rear roller
23 support plate 408, located in the plane of and adjacent to the front roller plate 400, provides a
24 surface to which other structures of the additive applicator 70 are mounted. Components of the
25 additive applicator apparatus 70, including rollers 78, 82 and support plates 400, 408 are
26 manufactured from materials such as stainless steel or hardened carbon steel. Several fixed or
27 rotatable guide rollers 420, 422, 424, 426, 428 are suitably fixedly mounted; such as to either the
28 front roller plate 408 or rear roller plate 410, depending upon the desired location of those guide
29 rollers. Those guide rollers provide the path over which the paper web 55 travels from a bobbin
30 (not shown), past the additive applicator 70, and on to other downstream destinations of the
31 cigarette making machine assembly.

1 The additive applicator 70 also includes a manifold 444 positioned above an additive
2 material reservoir 448, which is defined by the positioning of a reservoir front arm 452 and a
3 reservoir rear arm 454. Those arms 452, 454 are positioned above the pick-up roller 78. Tubing
4 458, or other suitable supply means, is connected to the manifold 444 and originates at a source
5 of additive material (not shown) to provide an input of additive material to reservoir 448, and
6 hence to the roll face of the pick-up roller 78. That portion of the additive applicator assembly
7 thus provides a sealed path for flow of additive material to the region where that additive
8 material is deposited onto the pick-up roller. Preferably, the reservoir front arm 452 and rear arm
9 454 each include at least one port (not shown), located on the bottom sides of each of those arms
10 452, 454. At least one of those ports is an output port through which additive material is
11 supplied to the roll face of the pick-up roller 78. At least one other port is an input port through
12 which a suction pump (not shown) suctions excess additive material from the edges of the pick-
13 up roller 78, and pumps excess additive material back into the reservoir 448 defined by arms
14 452, 454. The assembly also includes a collection pot 465 positioned adjacent to and slightly
15 below the pick-up roller 78. The collection pot 465 serves as a temporary collection location for
16 excess additive material removed from the pick-up roller 78.

17 The manifold 444 is attached to a glue manifold pivot plate 470, which is attached to the
18 front roller plate 400 and the rear roller plate 408. Such attachment leaves the manifold 444 with
19 the capability of moving upward and downward about a manifold pivot pin (not shown).
20 Movement of the manifold 444 upward from the operative position allows access to those
21 regions located below the manifold. Access to that region is desirable have access to the
22 reservoir arms 452, 454, to insert, remove and service the pick-up roller 78, and for maintenance
23 and service of the collection pot 465. In addition, the reservoir arms 452, 454, are movable
24 upward and downward about a reservoir pivot shaft (not shown) to allow access to the pick-up
25 roller 78 and the collection pot 465.

26 The transfer roller 82 and the pick-up roller 78 are positioned into operative engagement
27 with one another using a roller pressure plate 480. The roller pressure plate 480 is operably
28 connected to an air cylinder 484, or other suitable means for applying force to rollers 78, 82.
29 The air cylinder 484 utilizes compressed air to force the roller pressure plate 480 about a
30 pressure plate pivot shaft 488 into and out of engagement with the transfer roller 82. Movement
31 of the roller pressure plate 480 to engage and disengage the pick-up roller 78 with the transfer

1 roller 82 can programmed, and as such a microprocessor associated with the operation of the
2 cigarette making machine can be used to control movement of that plate 480.

3 The additive applicator 70 further comprises a roller lift bracket 495 mounted to the front
4 roller plate 400, and that lift bracket is movable. The roller lift bracket 495 includes a pair of
5 rollers 500, 505, or other suitable means for controlling the path of travel of the paper web 55.
6 The roller lift bracket 495 is operably connected to an air cylinder 510, or other suitable means
7 for applying force to the lift bracket. The air cylinder 510 also is connected to a supply of
8 pressurized air by an air tube 512, or other suitable connection and supply means. The air
9 cylinder 510 utilizes compressed air to move the pair of rollers 500, 505 on the roller lift bracket
10 495 into and out of rotating contact with the advancing paper web 55. For example, when the
11 rollers 500, 505 on the roller lift bracket 495 move downward into contact with the paper web
12 55, that paper web is likewise moved into rotating contact with roll face of the transfer roller 82.
13 As a result of the contact of the paper web 55 with the transfer roller 82, the additive material
14 applied to the transfer roller is transferred to the inside surface of the paper web, in a desired
15 pattern or fashion. Movement of the roller lift bracket 495 and rollers 500, 505 into and out of
16 contact with the paper web 55 can programmed, and as such a microprocessor associated with
17 the operation of the cigarette making machine can be used to control movement of that bracket
18 495. The roller lift bracket 495 can be controlled by a signal received from the cigarette making
19 machine, in order that the bracket can be retracted and the paper web 55 can be moved so as to
20 not be in contact with the various rollers when the cigarette making machine is not in normal
21 operation; and as such, problems associated with sticking of the paper web to various
22 components of the applicator apparatus 70 are minimized, avoided or prevented.

23 In operation, during the process of cigarette manufacture, the pick-up roller 78 is rotated
24 counter-clockwise, and the transfer roller 82 is rotated clock-wise. Those rollers are engaged in
25 contact by pressure supplied by the pressure plate 480. Additive material is fed from a source
26 (not shown) to the manifold 444, and from the manifold to the reservoir 448, from the reservoir
27 to the roll face of the pick-up roller 78, and onto the transfer roller 82. The additive material
28 then is transferred from the transfer roller to the paper web 55 as the paper web advances across
29 the surface of the rotating transfer roller 82. That is, as the paper web 55 advances across the
30 surface of the rotating transfer roller 82, the roller lift bracket 495 is moved downward, and the
31 rollers 500, 505 attached to that roller lift bracket are moved into contact with the advancing

1 paper web 55. As a result, the additive material on the surface of the transfer roller 82 is
2 transferred to the inside surface of the advancing paper web 55 at locations corresponding to the
3 pattern on the roller face of the transfer roller 82. The paper web 55 having additive material
4 applied thereto then is advanced to downstream locations of the cigarette making machine.

5 Referring to Figure 4, there is shown a portion of an additive applicator apparatus 70
6 representative of one aspect of the present invention. The pick-up roller 78 and the transfer
7 roller 82 are shown roll contact with one another and in operative engagement. Pick-up roller
8 possesses a roll face having a pattern of recessed grooves, or pockets, 535, 537, 539, 541, 543,
9 having the form of spaced bands, or other desired pattern. Those recessed grooves provide a
10 location for a predetermined amount of additive material to be deposited, and the size and shape
11 of those grooves is a matter of design choice. The pick-up roller 78 is rotated using a pick-up
12 drive shaft 550 (shown as cut away); and the transfer roller 82 is rotated using an applicator drive
13 shaft 554 (shown as extending from opening 556 in the applicator drive shaft box 558. The drive
14 shafts 550, 554 extend through an opening 560 in the front roller support plate 400, which is
15 adjacent the rear roller support plate 408. The pick-up roller 78 and the transfer roller 82 are
16 adapted to extend beyond the front faces of each of the front and rear roller plates 400, 408.

17 The applicator drive shaft box 558 is adapted to be positioned and secured to the back
18 side of the front and rear roller plates 400, 408. A pick-up roller gear 580 is in operative
19 connection with the pick-up drive shaft 550. A transfer roller gear 584 is in operative connection
20 with the applicator drive shaft 554. Both gears 580, 584 are located external to the applicator
21 drive shaft box 558, and are positioned on the back side of that drive shaft box 558. Those gears
22 580, 584 have interlocking teeth such that rotation of one of those gears in one direction causes
23 rotation of the other gear in the opposite direction. The transfer roller gear 584 is connected to a
24 transfer roller pulley 590. A belt 595 extends about the transfer roller pulley 590 and around a
25 power source pulley (not shown). As a result, power for rotational movement is provided to the
26 transfer roller shaft 550 and transfer roller 82 by rotation of the pulley 590 by movement of the
27 belt 595; and power for controlled rotational movement is provided to the pick-up roller 78 by
28 way of the drive shaft 550 that is rotated by operation of gears 580, 584. In addition, belt 595
29 can act as a timing belt, and by suitable use of that belt to control the speed of the applicator
30 drive shaft 554 relative to the speed of operation of the cigarette making machine, it is possible
31 to provide integral timing with the cigarette rod subdivision mechanism (not shown) of the

1 cigarette making machine. Thus, appropriate use of belt 595 to connect appropriate gear
2 mechanisms yields a method for providing pattern (e.g., band) registration for each individual
3 finished cigarette rods (not shown) that are cut from the continuous rod (not shown).

4 The applicator assembly 70 of the present invention can further include a photoelectric
5 sensor switch (not shown) located above a point of roller engagement between the pick-up roller
6 78 and the transfer roller 82. An exemplary sensor is a WT 12-2P430 from Sick, Inc. Output
7 from the photoelectric proximity switch is sent to a PLC or other suitable processor (not shown)
8 associated with that photoelectric sensor (not shown) and monitors the amount (e.g., level) of
9 additive material (not shown) in the region above that point of roller engagement of rollers 78,
10 82. Thus, as a flow of additive material is supplied from the manifold 44 and reservoir 448, an
11 amount of the additive material forms at the point of engagement between those rollers 78, 82.
12 When the amount of that additive material supplied to that region drops below a predetermined
13 level for sufficient desired transfer of the additive material to the transfer roller 82, the
14 information sensed and supplied by photoelectric sensor controls a switch to activate a pump (not
15 shown), and hence to supply more additive material to the reservoir 448. Similarly, deactivation
16 of the pump can be controlled when a desired level of additive material is achieved.

17 The applicator assembly 70 can further include sensors (not shown) that assist in ensuring
18 that proper amounts of additive material is transferred to the paper web. For example, an
19 induction-type sensor (not shown) located in the region of a pick-up roller 78 can sense that the
20 pick-up roller, and other associated components of the applicator assembly, are in proper
21 position. In addition, the cigarette making machine can be programmed such that when the
22 induction sensor detects that the pick-up roller is not in proper position, that machine can provide
23 appropriate signal to the operator or cease operation. In addition, a further sensor (not shown)
24 can be mounted on the rear roller plate 408 at a location of the paper web after that paper web
25 has passed over the transfer roller 82. That further sensor can be used to detect the presence, or
26 degree of presence, of additive material on the paper web 55. Detection of a sufficient presence
27 of additive material on the paper web 55 indicates that additive material transfer mechanisms are
28 operating properly. The cigarette making machine can be programmed to alert the machine
29 operator or stop movement of the paper web 55 if the further sensor detects an insufficient
30 presence of the additive material on the paper web 55.

1 Referring to Figure 5, there is shown a portion of a cigarette making machine assembly 8
2 of the present invention; and there also are shown relevant components of another representative
3 embodiment of an additive applicator apparatus 70 of the present invention. Such an applicator
4 70 is particularly useful for applying to a paper web 55 more viscous additive materials, than
5 those embodiments described previously with reference to Figures 3 and 4. More viscous
6 additive materials useful in applications involving cigarette paper include, for example,
7 formulations of additive materials having viscosities of greater than 100,000 centipoise. Such
8 higher viscosity additive materials can be characterized as pastes.

9 Additive applicator 70 is an assembly that includes a major pick-up/transfer roller 720
10 and a transfer pressure roller 725 (or back-up roller) mounted adjacent to each other and through
11 a front roller plate 730 secured to front exterior of a cigarette making machine. Each of a
12 plurality of rollers 422, 426, 428 is fixedly mounted to the front roller plate 730; and those rollers
13 provide guides for a path over which the paper web 55 travels from a bobbin (not shown) to the
14 additive applicator 70 and on to other regions of the cigarette making machine 8.

15 Positioned adjacent to the major roller 720 is a reservoir 740 for the additive material.
16 The reservoir is maintained in place and secured to the front roller plate 730 by bolts (not shown)
17 or other suitable connection means. The reservoir 740 is connected to a source (not shown) of
18 additive material (e.g., a formulation having the form of a paste), through port 742 near the top
19 region of the reservoir 740. As such, a source of additive material for the major roller 720 is
20 provided. Typically, the additive material is supplied through tubing (not shown), such as
21 Tygon-type tubing, that feeds the reservoir 740 through port 742. The additive applicator 70
22 provides a sealed path for flow of the additive material to the point of deposit onto the major
23 roller 720. The reservoir 740 includes at least two ports (not shown) on the side thereof adjacent
24 to the major roller 720. One port is an output port positioned near the middle of the reservoir
25 740, through which additive material is supplied to the major roller 720. At least one other port
26 is an input port through which excess additive material is scraped from the edges of the major
27 roller 720, and is fed back into the reservoir 740.

28 The reservoir 740 is attached to an assembly that is designed to exert pressure upon that
29 reservoir. Such a pressure exerting assembly includes a reservoir pad 748 that is positioned
30 adjacent to the reservoir 740. The reservoir pad 748 is held in position by a reservoir pad
31 retainer 753, which encompasses the reservoir pad 748. Compression springs 756, 758 are

1 positioned between the reservoir pad retainer 753 and a reservoir spring retainer 761, and
2 provide resistance for tightening of the reservoir spring retainer 761 toward the reservoir 740.
3 Screws 765, 767, or other suitable connection means, are positioned through each side of the
4 reservoir spring retainer 761, through the center of each respective compression spring 756, 758,
5 and through a passage in each side of the reservoir pad retainer 753. The screws 765, 767 are
6 movable in and out of respective passages 770, 772 of the reservoir pad retainer 753. The
7 threaded ends of the screws 765, 767 are positioned in threaded contact with threaded walls of
8 the passages 770, 772 of the reservoir pad 748 so as to supply the application of pressure to the
9 reservoir pad 748 when pressure is exerted against the reservoir spring retainer 761.

10 An adjustment screw mounting plate 778 is attached to the front roller plate 730 adjacent
11 to the reservoir spring retainer 761. An adjustment screw 781 is threaded through the adjustment
12 screw mounting plate 778 into contact with the reservoir spring retainer 761. When the
13 adjustment screw 781 is adjusted a predetermined amount inward into increasingly compressive
14 contact with reservoir spring retainer 761, pressure is applied by the screws 765, 767 to the
15 reservoir pad 748. As a result, a predetermined amount of pressure is exerted on the paste
16 reservoir 740. The additive material formulation is caused to flow to the reservoir 740 by
17 application of head pressure supplied from an upstream pumping system (not shown) or other
18 suitable means. The additive applicator 70 also can be equipped with sensors and control
19 devices (not shown) of the type described previously with reference to Figure 4.

20 A scraper plate 783 is connected to the reservoir 740. A compression spring 785 is
21 positioned between a scraper 783 and the scraper plate 787 such that the scraper is urged into
22 operative contact with the roll face of the major roller 720. As such, excess additive material on
23 the surface of the roll face of the major roller 720 is scraped from that roll face as the moving
24 major roller passes the scraper, and that material is deposited back into the reservoir 740. Thus,
25 additive material carried by the major roller 720 for transfer to the paper web is located in the
26 desired location; within the pockets located on the roll face of that roller.

27 Rollers 790, 792, 794 together with transfer pressure roller 725 are positioned on a roller
28 lift bracket 798. The roller lift bracket 798 is designed to be moved downward by the forces
29 applied by air cylinder 805 about a lift bracket pivot plate 806. The air cylinder 805 is connected
30 to a source of pressurized air (not shown), and is employed to provide for movement of the roller
31 lift bracket 798. The roller lift bracket 798 is attached on one end to the front roller plate 730

1 about lift bracket pivot plate 806 through roller lift bracket pivot pin 807, and the lift bracket 798
2 is movable. The roller lift bracket 798 further includes a lift bracket pivot sleeve 808, which is
3 slidably attached on the end opposite the pivot pin 807 to lift bracket pivot plate 806.

4 In operation, the transfer pressure roller 725 and rollers 790, 792, 794 can be moved
5 about the pivot pin 807 so as to be positioned into and out of contact with the upper surface of
6 the paper web 55. When the transfer pressure roller 725 is moved into operative contact with the
7 major roller 720, the transfer pressure roller 725 rotates under the power of the major roller 720,
8 but in the opposite direction to that of the major roller. Preferably, the major roller 720 rotates
9 clockwise, and the transfer pressure roller 725 rotates counter-clockwise. The transfer pressure
10 roller 725 thus preferably contacts the advancing paper web 55 at a point of engagement of the
11 roll faces of the transfer pressure roller 725 and the major roller 720. As a result of the pressured
12 contact experienced by the paper web 55 as it travels between transfer pressure roller 725 and the
13 major roller 720, additive material is applied to the paper web 55 in a predetermined pattern.
14 Movement of the roller lift bracket 798, transfer pressure roller 725, and rollers 790, 792, 794
15 into and out of contact with the paper web 55 can be programmed, and as such a microprocessor
16 associated with the operation of the cigarette making machine can be used to control movement
17 of that lift bracket 798. The roller lift bracket 798 can be controlled by a signal received from
18 the cigarette making machine, in order that the bracket can be retracted and the paper web 55 can
19 be moved so as to not be in contact with the various rollers when the cigarette making machine is
20 not in normal operation; and as such, problems associated with sticking of the paper web to
21 various components of the applicator apparatus 70 are minimized, avoided or prevented.

22 Referring to Figure 6, there are shown relevant components of a portion of an additive
23 applicator apparatus 70 representative of one aspect of the present invention. The major roller
24 720 possesses a roll face having a pattern of recessed grooves or pockets 820, 822; thus
25 providing a pocketed wheel. The diameter of the major roller can vary, but suitable major roller
26 has a diameter of about 104 mm. Exemplary grooves provide spaced bands located so as to
27 extend perpendicularly to the longitudinal axis of a paper web and across a portion of the width
28 of that paper web, and are generally box-like in shape. The dimensions of the grooves can vary,
29 and are dependent upon factors such as the pattern of application that is desired; but suitable
30 grooves have depths of about 2 mils, longitudinally extending lengths of about 5 mm, and
31 transversely extending lengths of about 23 mm. Those grooves 820, 822 are designed to contain

1 additive material (not shown) and to transfer that additive material to a paper web (not shown)
2 that contacts that roller face as the paper web travels past the roll face of the major roller 720.
3 As such, for the pattern shown, spaced apart bands are applied at predetermined intervals
4 transversely to the longitudinal axis of the continuous paper web. That is, the recessed grooves
5 820, 822 provide a location for a predetermined amount of additive material to be deposited on a
6 paper web; and the size and shape of those grooves is a matter of design choice. The major roller
7 720 is manufactured from materials such as stainless steel, hardened carbon steel, or the like.

8 The roller lift bracket 798 supports rollers 790, 792, 794 and back-up roller 725. Back-up
9 roller 725, or "soft-faced" roller, typically is manufactured from stainless steel or hardened
10 carbon steel, and the roll surface is provided by an overlying band or ring of a suitable material
11 such as a rubber-type or elastomeric material. Suitable "soft-faced" rollers 725 are adapted from
12 those types of commonly used for component parts of conventional cigarette making machines,
13 and are manufactured from materials commonly used in conventional cigarette making
14 machines. The roller lift bracket also supports the air cylinder 805 and the pivot plate 806. The
15 diameter of the back-up roller 798 can vary, but a suitable back-up roller has a diameter of about
16 40 mm.

17 The reservoir 740 for the additive material is assembled along with the reservoir spring
18 retainer 761, the adjustment screw mounting plate 778, the adjustment screw 781, scraper 783
19 and the scraper plate 787.

20 Positioned on the front roller plate 730 are a plurality of rollers 422, 426, 428 and an
21 opening 824. The major roller 720 is connected to a roller drive shaft 828 that passes through
22 opening 824 and to an applicator drive shaft box 830 that is in turn connected to a roller gear
23 834. A belt 595 extends about the roller gear 834 and around a pulley 838 mounted to a power
24 drive assembly 841. Rotational power is provided from the power drive assembly 841 to the
25 roller gear 834 to the roller shaft 828 and to the major roller 720. Timing belt pulley 842 can be
26 used to receive input regarding the speed of operation of the cigarette making machine, and
27 hence can be use in conjunction with a belt (not shown) to time operation of the other
28 components of the applicator apparatus 70.

29 Referring to Figure 7, there are shown relevant components of a portion of yet another
30 additive applicator apparatus 70 representative of one aspect of the present invention. Other
31 components of the additive applicator apparatus, and the general operation thereof, are described

1 previously with reference to Figures 5 and 6. Such an applicator 70 is particularly useful for
2 applying to a paper web 55 more viscous additive materials. More viscous additive materials
3 useful in applications involving cigarette paper include, for example, paste-type formulations of
4 additive materials having viscosities of greater than 100,000 centipoise.

5 Additive applicator 70 is an assembly including a major pick-up/transfer roller 850 that is
6 generally similar to that pocketed roller described previously with reference to Figures 5 and 6.
7 For example, the diameter of the major roller 850 can be about 104 mm, and the major roller can
8 be manufactured from materials such as stainless steel, hardened carbon steel, and the like.
9 Several rollers (not shown) are fixedly mounted to the front roller plate 730; and those rollers
10 provide guides for a path over which the paper web 55 travels from a bobbin (not shown) to the
11 additive applicator 70, between the roll faces of major roller 850 and back-up roller 725, and on
12 to other regions of the cigarette making machine 8.

13 Positioned adjacent to the major roller 850 is a reservoir 855 for the additive material.
14 The reservoir is maintained in place and secured to the front roller plate 730 by bolts (not shown)
15 or other suitable connection means. The reservoir 855 is connected to a source (not shown) of
16 additive material (e.g., a formulation having the form of a paste), through the top region of the
17 reservoir 855. As such, a source of additive material for the major roller 850 is provided. A
18 portion of the reservoir 855 is shown in phantom in order to show more clearly the positioning of
19 a portion of the major roller 850 within the reservoir, and to more clearly show the positioning of
20 the scrapers 860, 864 against the roll face and side, respectively, of the major roller. Typically,
21 the additive material is supplied through tubing (not shown), such as Tygon-type tubing, that
22 feeds the reservoir 850 through a port (not shown). The additive applicator 70 provides a path
23 for flow of the additive material to the point of deposit onto the major roller 850.

24 A scraper 860 is connected to the body of the reservoir 855. The scraper 860 is urged
25 into operative contact with the roll face of the major roller 850. As such, excess additive
26 material on the surface of the roll face of the major roller 850 is scraped from that roll face as the
27 moving major roller passes the scraper, and that material is deposited back into the reservoir 855.
28 Thus, additive material carried by the major roller 850 for transfer to the paper web is located in
29 the desired location; within the pockets located on the roll face of that roller. Against the front
30 side face of major roller 850 is positioned a scraper 864. A corresponding scraper (not shown) is
31 positioned against the back side face of the major roller 850. As such, the roll face and both side

1 faces are subjected to surface treatment by three scraper pieces arranged in a “U”-like
2 configuration, so as to remove undesirable excess additive formulation from those surfaces, and
3 hence, maintain those surfaces relatively clean by maintaining those surfaces relatively free of
4 build up of coating formulation.

5 Referring to Figure 8, there is shown one finger rail 925 of a finger rail assembly
6 representative of one aspect of the present invention. That finger rail 925 is referred to as the
7 “outside” finger rail, and an exemplary finger rail has a length of about 22 cm. Exemplary finger
8 rails and finger rail assemblies that can be modified in accordance with one aspect of the present
9 invention are commercially available, and the design and use of finger rails and finger rail
10 assemblies in cigarette making machines will be readily apparent to those skilled in the art of
11 cigarette making machine design and operation.

12 Finger rail 925 includes a downwardly extending outside finger rail protrusion or
13 projecting arm 928 that gradually narrows to form a blade-like lower face 929. At its garniture
14 end 931, the bottom portion of the finger rail 925 curves gradually upward and with a gradually
15 increasing angle towards the extreme garniture end 931. The finger rail 925 is adapted to include
16 an air chamber or manifold 934, or other means for distributing and defining passage of air flow
17 within the finger rail. A typical manifold 934 has a length of about 15 cm, a width of about 5
18 mm, and a depth of about 4 mm. Such a manifold 934 can be provided by drilling out, or
19 otherwise fashioning, that region of a conventional finger rail that is manufactured from a
20 material such as stainless steel, hardened carbon steel, or other suitable metal alloys. Preferably,
21 as shown, the manifold is aligned so as to extend lengthwise in a generally parallel manner
22 relative to the axis that defines the length of the finger rail. The finger rail 925 also includes an
23 air passageway 947 extending through the finger rail and into the manifold 934, near the
24 garniture end 931 of that finger rail; and as such an air passageway extends entirely through the
25 finger rail. The air passageway 937 provides a path for the flow of air into the manifold 934 that
26 is supplied from a source of pressurized air (not shown) through a tube or other suitable
27 connection means (not shown) from the back side of the finger rail 925 (i.e., the air passageway
28 937 provides a means for introducing air flow to the air distribution means).

29 Extending generally downward from the manifold 934 and along the outside face of the
30 finger rail 925 are several narrow air channels 940, 941, 942. Those air channels, grooves or
31 passageways are formed, drilled, cut, etched or otherwise fashioned in the lower region of the

1 finger rail 925 along the length of the manifold. Thus, the air flow passageways 940, 941, 942
2 are in air flow communication with the manifold, and those air flow passageways provide for
3 exit of high velocity air flow from the finger rail. The number of air channels can vary, and can
4 be a manner of design choice. However, the number of air flow passageways typically can range
5 from about 15 to about 30, with about 18 to about 28 being preferred. Typically, the air flow
6 passageways are spaced about 6 mm apart, and the width of each air flow passageway is about
7 20 mils. The plurality of air channels 940, 941, 942 can be positioned in a random or
8 predetermined pattern, and the air channels all can point in the same direction (e.g., generally
9 downward) or air channels can multi-directional in nature (e.g., the air channels can point
10 generally downward, downward and inwardly, downward and outwardly, and the like).

11 The finger rail 925 further includes a manifold cover (not shown), that covers the outer
12 side of the finger rail in order that air flow from the air passageway 937 passes through the
13 manifold 934 and out the plurality of air channels 940, 941, 942 directed out from the bottom of
14 the finger rail. The manifold cover typically has the form of a metal plate that is secured in place
15 to the finger rail 925 over the manifold 934 using epoxy-type cement, spot weld, or other suitable
16 means. Covering the manifold 934 ensures the desired passage of high velocity air out of the air
17 passageways 940, 941, 942.

18 Referring to Figure 9, there is shown one finger rail 950 of a finger rail assembly
19 representative of one aspect of the present invention. That finger rail 950 is referred to as the
20 “inside” finger rail, and is designed to form a finger rail assembly when used in conjunction with
21 the “outside” finger rail previously described with reference to Figure 8. The overall design and
22 appearance of the inside finger rail 950 is generally similar in many regards to that of the
23 previously described outside finger rail. However, the corresponding finger rails are designed to
24 have a somewhat “mirror image” or a “left handedness/right handedness” relative to one another.

25 At its garniture end 952, the bottom portion of the finger rail 950 curves gradually
26 upward. The finger rail 950 also is adapted to include an air chamber 954 or manifold. The
27 finger rail 950 also includes an air passageway 956 extending through the finger rail and into the
28 manifold 954, near the garniture end 952 of that finger rail. Extending downward from the
29 manifold 954 along the outside face of the finger rail 950 are several narrow air channels 960,
30 961, 962. Those air channels are formed, drilled, cut, etched or otherwise fashioned in the lower
31 region of the finger rail 925 along the length of the manifold. Most preferably, those air channels

1 960, 961, 962 are positioned in a staggered, pattern along the lower region of the manifold 954.
2 The finger rail 950 further includes a manifold cover (not shown).

3 Referring to Figure 10, there is shown one finger rail 980 of a finger rail assembly
4 representative of another aspect of the present invention. That finger rail 980 is referred to as the
5 “outside” finger rail. Exemplary finger rails and finger rail assemblies that can be modified in
6 accordance with this aspect of the present invention also are commercially available, and the
7 design and use of finger rails and finger rail assemblies in cigarette making machines will be
8 readily apparent to those skilled in the art of cigarette making machine design and operation.

9 The overall design and appearance of finger rail 980 is generally similar in many regards
10 to that of the outside finger rail previously described with reference to Figure 8. The finger rail
11 980 is adapted to include a generally longitudinally-extending relief channel 982 cut or otherwise
12 fashioned along the lower outer face of the finger rail. The finger rail 980 includes a tube 985
13 for air passage, and preferably, the tube has a generally circular cross sectional shape. The tube
14 985 extends along the relief channel 982, and as such, the tube is aligned so as to extend
15 lengthwise in a generally parallel manner relative to the axis that defines the length of the finger
16 rail. The tube 985 is secured to the finger rail 980 using epoxy-type cement, spot weld, or other
17 suitable attachment means. The tube 985 provides a path for the flow of air that is supplied to
18 the other end of that tube from a source of pressurized air (not shown) through a tube or other
19 suitable connection means (not shown) from a region relatively remote from the finger rail 980.
20 That is, it is preferable that one end 986 of the tube 985 is open to receive a source of high
21 velocity air, and the other end 987 of tube 985 is sealed or closed to as to prevent the exit of air
22 flow therefrom. The inner diameter of tube 985 can vary, but typically such a tube can have an
23 inner diameter of about 2 mm to about 5 mm.

24 The tube 985 includes a plurality of air distribution outlets 988, 989, 990 that extend
25 along its length, and in its lower region; such that air passing through the tube flows out of those
26 outlets and is directed generally downward. As such, the tube 985 is in functional alignment
27 with the finger rail. A typical tube 985 possesses air distribution outlets extending about 15 cm
28 along its length. The air distribution outlets 988, 989, 990 are a series of small openings or
29 narrow passageways arranged, and those passageways can be positioned in a predetermined,
30 random or staggered pattern. By “staggered” is meant that the various air channels are arranged
31 in a non-linear fashion, the distances between individual air channels are not necessarily all the

1 same, or the various air channels direct air in different directions. One representative pattern of
2 air channels is composed of two longitudinally-extending rows that are offset from one another
3 (e.g. in a zig zag type pattern), and the openings of the inside row are designed to direct air flow
4 generally straight downward, and the openings of the outside row are designed to direct air flow
5 downward and outward.

6 The dimensions of the air passageways 988, 989, 990 can vary, but suitable air
7 passageways are small openings. The cross sectional shape of those openings can vary, but
8 suitable openings of generally circular cross sectional shape often are about 20 mils in diameter.
9 Normally, the number of those narrow air channels extending downward from the tube 985
10 ranges from about 15 to about 30, with about 18 to about 28 being preferred.

11 Referring to Figure 11, there is shown one finger rail 995 of a finger rail assembly
12 representative of one aspect of the present invention. That finger rail 995 is referred to as the
13 “inside” finger rail, and is designed to form a finger rail assembly when used in conjunction with
14 the “outside” finger rail previously described with reference to Figure 10. The overall design
15 and appearance of the inside finger rail 995 is generally similar in many regards to that of the
16 outside finger rail previously described with reference to Figure 10. The finger rail 995 also is
17 adapted to include tube 998 for air passage. Extending downward from the tube 998 are several
18 narrow air channels 1005, 1006, 1007, preferably in a staggered arrangement. Those air
19 channels are located in the lower region of the finger rail 995 along a portion of the length of the
20 tube 998.

21 The finger rails that are described with reference to Figures 8 through 11 are properly
22 assembled into finger rail assemblies on cigarette making machines. In operation, those finger
23 rail assemblies are provided with a supply of pressurized air that enters the relevant air
24 passageways and chambers of the finger rails. That moving air then passes out of the numerous
25 air distribution outlets that direct the flow of air generally downward. The relative dimensions
26 (e.g., the inside diameters) of the various air distribution outlets depend upon factors such as the
27 desired rate of air flow and related fluid dynamics. For most applications, an air flow rate is
28 determined by experimentation, and the amount of airflow employed to provide the desired or
29 optimum operation is a matter of design choice. In a preferred embodiment, the supply of
30 pressurized air provides a continuous flow of air sufficient to reach each air distribution outlet
31 along the length of an air supply tube or manifold, such that a substantially equal rate of air flow

1 from each air distribution outlet is achieved. A consistent air flow rate from each finger rail air
2 distribution outlet in a staggered pattern has the tendency to promote formation of the desired
3 turbulent air flow pattern below the finger rail assembly.

4 Referring to Figure 12, there is shown an embodiment of another aspect of the present
5 invention. A modified garniture entrance cone 144 is designed to be positioned within a
6 cigarette making machine in a region below the finger rail assembly (not shown). Exemplary
7 entrance cones that can be modified in accordance with one aspect of the present invention are
8 commercially available, and the design and use of entrance cones in cigarette making machines
9 will be readily apparent to those skilled in the art of cigarette making machine design and
10 operation. An exemplary garniture entrance cone has a length of about 23 cm, a width of about 5
11 cm and a maximum height of about 2 cm. Typically, the entrance cone is manufactured from
12 materials such as stainless steel, hardened carbon steel, aluminum alloys, and the like. Modified
13 entrance cones can be of multi-piece construction, such as is shown in Figure 12, or one-piece
14 construction.

15 Garniture entrance cone 144 includes a downstream section 1020, an upstream section
16 1022, and a modified upper insert 1024 for a portion of the upper region of the upstream section.
17 The entrance cone 144 possesses a generally concave upper surface 1030. Within that upper
18 surface 1030 are opposing longitudinally-extending lower lateral aspects 1035, 1037, and within
19 the upstream section 1022 are corresponding opposing upper lateral aspects 1040, 1042. Each of
20 the lower lateral aspects and each of the upper lateral aspects are positioned on opposite sides of
21 a longitudinally-extending concave upper surface 1030.

22 An entrance cone 144 of the type of the present invention also includes a first
23 longitudinal-extending air flow passage slot or gap 1050 located between lower lateral aspect
24 1035 and upper lateral aspect 1040; and a second longitudinally-extending front air flow passage
25 slot or gap 1052 located between the lower lateral aspect 1037 and upper lateral aspect 1042.
26 Preferably, the overall shapes of the two slots on each side upper portion of the upstream section
27 1022 of the entrance cone are such that those slots are mirror images of one another. Typically,
28 the width of each slot ranges from about 0.5 mil to about 3 mils, with about 1 mil to about 2 mils
29 being preferred. The entrance cone 144 includes an air entrance chamber 1060 on the bottom
30 side of the entrance cone, or in any other suitable location. An exemplary air entrance chamber
31 or port 1060 is a tube-like member that provides a generally circular air entrance opening of

1 about 9 mm in diameter. A source of air for a fast moving air stream is provided from a suitable
2 source, such as a laboratory-type pressurized or compressed air source (not shown), and the air
3 entrance chamber 1060 is suitably connected to the supply of pressurized air by a suitable
4 connection means, such as Tygon-type tubing or the like. The air flow introduced through the air
5 entrance chamber 1060 preferably passes through a manifold or passageway system (not shown)
6 located within the entrance cone, and passes out of the longitudinally extending air slots 1050,
7 1052. For an exemplary entrance cone, those air slots 1050, 1052 preferably are positioned so as
8 to extend length-wise about 14.5 cm. As such, the air slots 1050, 1052 extend along the entrance
9 cone 144 that distance that the finger rail assembly (not shown) overlies the finger rail when
10 configured under normal assembly within a cigarette making machine; however, the air slots can
11 extend a lesser distance or a greater distance. Those slots also each can be positioned at angles
12 that extend upward and outward. Typically, the angles are at least about 45° relative to
13 horizontal at the extreme upstream end of the entrance cone 144; and the angles gradually
14 becomes steeper along the length of the entrance cone, such that the angles are at least about 75°
15 at the extreme downstream ends of those slots. As such, that air flow is directed from slot 1050
16 toward the upper lateral aspect 1040, and from slot 1052 upwards and outwards toward the upper
17 lateral aspect 1042.

18 Referring to Figure 13, the representative garniture entrance cone 144 includes
19 downstream section 1020 that is longitudinally aligned with upstream section 1022. Those
20 sections are maintained in place relative to one another using male pegs (not shown) that are
21 inserted into cooperating female grooves 1054, 1056. Preferably, for an entrance cone of about
22 23 mm total length, the upstream section has a length of about 14.5 mm. Typically, the length of
23 the upper insert 1024 and the entire length of the upstream section 1022 are essentially equal to
24 one another. Normally, the lengths of the upstream section 1022 and the upper insert 1024, and
25 the positioning of each of those sections, correspond to that region of the entrance cone 144 that
26 is located immediately below the overlying portion of the finger rail assembly (not shown), when
27 those components are properly assembled within a cigarette making machine (not shown). The
28 upper insert 1024 is designed to provide the designed concave surface structure to a portion of
29 the upper surface of the garniture entrance cone 144. Beneath the upper insert 1024 is provided a
30 cavity 1058 that provides a type of manifold for air flow that is introduced through air inlet 1060.
31 For a representative upstream section 1022 having a length of about 14.5 cm, a suitable manifold

1 1058 has a length of about 14.5 cm, a depth of about 0.5 mm to about 1 mm, and a width of
2 about 7 mm to about 15 mm. Thus, air entering the manifold 1058 passes out of the slots or
3 grooves (not shown) that are located between (i) the bottom and sides of the upper insert 1024,
4 and (ii) the top and sides of the upstream section 1022. The upper insert 1024 and the upstream
5 section 1022 are maintained in place relative to one another using appropriately located pegs and
6 grooves, and suitable adhesives materials (e.g., epoxy-type cement).

7 Referring to Figure 14, there is shown a region of a cigarette making machine 10,
8 representative of that of the types of cigarette making machines described previously with
9 reference to Figures 1 and 2. In particular, there is shown the entrance region of the garniture
10 section 45 of a cigarette making machine 10. There is shown a cross-sectional end view of a
11 finger rail assembly 140 that is representative of one aspect of the present invention and an
12 entrance cone 144 that has been adapted in accordance with another aspect of the present
13 invention. Additionally, there is shown tobacco filler 20 held by foraminous belt 32 that is
14 supported by roller 132 (shown as partially cut away). There also is shown garniture conveyor
15 belt 130 and paper web 55 having additive material 73 applied to one surface of that paper web.

16 The finger rail assembly 140 includes two complementary finger rails; that is front finger
17 rail 925 and back finger rail 950. The finger rails 925, 950 are of the type described previously
18 with reference to Figures 8 and 9, respectively. That is, each finger rail possesses a plurality of
19 spaced, downwardly extending air passageways from manifolds 934, 954, respectively. For the
20 cross-sectional view shown, the positioning of the air passageways is staggered; thus, the region
21 of the back finger rail 950 that is shown possesses a downwardly extending air passageway 960,
22 while the region of the front finger rail 935 shown is not a region where a downwardly extending
23 air passageway has been positioned. Manifold covers 1110, 1112 cover a portion of the outside
24 faces of finger rails 925, 959, respectively. Those manifold covers 1110, 1112 are secured in
25 place by suitable means, such as spot welds or epoxy-type cement.

26 The finger rails 925, 950 both are positioned in their normal essentially parallel, spaced
27 apart alignment above entrance cone 144, such that the downwardly projecting arms defined by
28 the shape of those finger rails form opposing sides of a substantially rectangular, longitudinally
29 extending passageway, channel or track 1120. The foraminous belt 32 and the tobacco filler
30 cake 20 supported and transported by that belt travel through the upper region of that track 1120.

1 A portion of the garniture entrance cone 144 includes a downwardly concave, or
2 semicircular, upper surface face 1030. As such, the passageway 1120 is defined by an upper
3 region or surface (provided by the foraminous belt 32), two side surfaces (defined by the
4 positioning of finger rails 925, 950) and lower surface (provided by the upper surface face 1030
5 of the entrance cone 144). The garniture conveyor belt 130 conveys the wrapper web 55 across
6 the upper surface 1030 of the entrance cone 144. After the tobacco filler 20 is deposited onto the
7 advancing paper web 55, the semicircular configuration of a portion of the upper surface 1030 of
8 the entrance cone 144 helps form the paper web 55 and the stream of tobacco filler 20 thereon
9 into a rod-like shape having the desired cross-sectional shape (e.g., generally circular). The
10 upper surface 1030 of the garniture entrance cone 144 can be chemically or physically surface-
11 treated, if desired. For example, the garniture entrance cone upper surface 1030 can be treated so
12 as to have a surface of a ceramic material having a low coefficient of friction.

13 Each of the opposing edges 1130, 1132 at each end of the inside surface 88 of the paper
14 web 55 can have the tendency to come into contact with the lower region of the finger rail
15 assembly 140, and in particular, the lower regions or downwardly protruding arms or portions of
16 each respective finger rail 925, 950. Typically, the inside surface 88 of portions of the paper web
17 55 come into contact with portions of the finger rail assembly 140 above the entrance cone 144.
18 When the inside surface 88 of the paper web 55 has been coated with an additive material 73
19 (that can have the form of an adhesive-type coating formulation), and the inside surface 88 of the
20 paper web 55 reaches the garniture entrance cone 144 and finger rail assembly 140, that additive
21 material still can be wet, tacky or sticky. As a result, some of that additive material 73 can
22 exhibit a tendency to stick onto portions of the finger rail assembly 140.

23 A fast moving gas stream exits the finger rail 140 assembly in the region in the bottom
24 region of finger rails 925, 950; but above the paper web 55. The fast moving gas stream is
25 provided from a suitable source, such as a laboratory-type pressurized or compressed air source
26 (not shown). The temperature of the gas can vary, and air of essentially ambient temperature,
27 heated air or cooled air can be used. Although not preferred for most applications, the gas
28 stream can comprise steam. Preferably, air flow is provided through a T-type connection tube
29 (not shown) connected to a supply tube such that air enters the air inlet passageways (not shown)
30 and into the respective manifolds 934, 954 through the respective back faces of each finger rail.
31 The downward force of the air stream, as well as a suitably designed pattern of airflow from the

1 finger rail assembly (e.g., such as a staggered pattern of air distribution outlets (not shown))
2 results in the creation of a zone of air turbulence above the paper web 55. The downward forces
3 created by such an air stream act to maintain the paper web 55, and particularly the opposing
4 edges 1130, 1132 thereof, spaced away from the adjacent surfaces of the finger rail assembly
5 140. Consequently, as the paper web 55 advances underneath the finger rail assembly 140, the
6 additive material 73 on the inside surface 88 of the paper web 55 is effectively prevented from
7 being transferred to lower regions of the finger rail assembly 140. As a result, the air above the
8 paper web 55 is sufficiently agitated to maintain the paper web a distance away from the lower
9 surfaces of the finger rails 925, 950. A staggered pattern of air distribution outlets assists in
10 avoiding the formation of a laminar-type air flow down onto the advancing paper web 55.
11 Certain downwardly directed air flows patterns (e.g., certain patterns that are not turbulent in
12 nature) can have a tendency to produce a zone of low air pressure above the paper web 55, and
13 such types of air flow patterns can result in the paper web being drawn into contact with the
14 lower surface region of the finger assembly 140.

15 Additionally, a fast moving gas stream can exit manifold 1058 through longitudinally
16 extending air slots 1050, 1052 extending within the upper surface 1030 of entrance cone 144 can
17 be positioned in alignment, such that air flow is directed toward the edges 1130, 1132 of the
18 paper web 55. The fast moving gas stream is provided from a suitable source (not shown). The
19 temperature of the gas can vary, and air of essentially ambient temperature, heated air or cooled
20 air can be used. Although not preferred for most applications, the gas stream can comprise
21 steam. The previously described downward force of the air stream provided from the modified
22 finger rail assembly 140, as well as a suitably designed pattern of airflow from the entrance cone
23 144, results in the creation of a low air pressure zone 1200 below the paper web 55. The
24 downward forces created by such an air stream act to maintain the paper web 55, and particularly
25 the opposing edges 1130, 1132 thereof, spaced away from the adjacent surfaces of the finger rail
26 assembly 140. That is, the paper web 55 is effectively drawn away from the finger rail assembly
27 140. Additionally, the entrance cone air outlets 1050, 1052, or other suitable air exit or
28 distribution means, are directed toward each of opposing edges of the paper web that overlies
29 that entrance cone. Thus, the direction of air flow through the longitudinal air slots 1050, 1052
30 of the entrance cone 144 relative to the edges 1130, 1132 of the paper web 55 causes the
31 formation of a low air pressure zone 1200 below the paper web 55. The edges 1130, 1132 of the

1 paper web 55 are caused to be drawn down onto the respective upper lateral aspects 1040, 1042
2 of the entrance cone concave upper surface 1030. Those edges 1130, 1132 are thereby
3 effectively pulled away from contact with components of the finger rail assembly 140. As a
4 result, transfer of the additive material 73 from the inside surface 88 of the paper web 55 is
5 avoided, minimized or prevented from being transferred to the finger rail assembly 140, as the
6 paper web 55 advances underneath that assembly.

7 Air flow from the finger rails 925, 950, from the entrance cone 144, or from a
8 combination of air flow from both the finger rails 925, 950 and from the entrance cone 144
9 allows air flow rates from above, below, or both from above and below, the paper web 55. As
10 such, a desirable smooth movement of the paper web 55 between the finger rail assembly 140
11 and the entrance cone 144 is facilitated, while maintaining the paper web 55 a desirable distance
12 away from components of the finger rail assembly. The degree of air flow through the finger
13 rails 925, 950 and through the entrance cone 144 that is sufficient to achieve optimum operation
14 can be determined by experimentation and can be a matter of design choice.

15 Referring to Figure 15, there is shown a block diagram of registration and inspection
16 systems 1500 representative of various aspects of the present invention. Such a system 1500 is
17 useful for inspecting and assisting in the control of manufacture of cigarettes (not shown) that are
18 manufactured from a continuous paper web 55 possessing a predetermined pattern, such as a
19 plurality of bands 1505, 1506, 1507, 1508. The paper web 55 is routed near a detection system
20 95. The detection system can be spectroscopic system, such as a non-contact ultrasonic
21 transmission system or a near infrared (NIR) absorption system. Such a detection system can be
22 characterized as a non-optical type of detection system. A typical detection system 95 includes a
23 transducer/sensor component 1510 and a processor/analyzer component 1512. A typical
24 ultrasonic detection system 95 utilizes a transducer and an analyzer. A preferred ultrasonic
25 detection system is available as Model NCT 210-P2 6.3mm 1MHz transducer 1510 and NCA-
26 1000 2 EN analyzer 1512, available from SecondWave Systems Corp. A typical NIR system 95
27 utilizes a sensor and a processor. A preferred NIR detection system utilizes a GD 100W NIR
28 sensor 1510 with a 100 microsecond response time and G-NET Verification System processor
29 1512, available from Nordson Corporation. Typically, detector systems 95 possess response
30 times sufficient to provide adequate information regarding a continuous paper web 55 that is
31 moving at speeds customary on conventional cigarette making machines.

1 NIR reflectance systems are particularly preferred spectroscopic systems for inspecting
2 samples, such as paper webs that are considered to be opaque. See, *Near-Infrared Technology in*
3 *the Agricultural and Food Industries*, edited by Phil Williams and Karl Norris, Published by the
4 American Association of Cereal Chemists, Inc. St. Paul, Minnesota, USA. Typically, the
5 radiation emission source and detector 1510 are housed in the sensor body, and a fiber optic
6 bundle guides the incident light to the paper web through a focusing lens in order to achieve a
7 spot size of about 3 mm. Typically, the reflected radiation is collected by the same lens and fiber
8 optic bundle, and directed back to the detector 1510. Such components of such a system
9 typically have a response time of about 100 microseconds, which is sufficiently fast to detect
10 bands on a cigarette making machine running at speeds sufficient to produce about 8,000
11 cigarette rods per minute, and having either 1 or 2 bands per cigarette rod. For example, for a
12 tobacco rod length of 60 mm, a nominal tobacco rod making speed of 8,000 rods per minute, and
13 a single band of adhesive of 5 mm width per rod, the detection time for each rod is about 625
14 microseconds.

15 NIR spectroscopy measures the chemical concentration of constituents in a sample in the
16 wavelength range of about 850 nm to about 2500 nm. Radiation within such wavelengths can be
17 generated using gratings, band pass interference filters, diodes or high speed electronically
18 controlled acousto-optic transmission filters (AOTF). Exemplary detectors used in NIR
19 spectrophotometric systems are lead sulfide (PbS), silicon (Si) and indium gallium arsenide
20 (InGaAs) detectors. NIR-based systems can be used to detect the presence of chemical
21 constituents, such as water, other components of the coating formulations applied to the paper
22 web, or marker materials that are incorporated into the coating formulations. For many additive
23 formulations that are applied to paper webs in accordance with the on-line application techniques
24 of the present invention, those formulations incorporate water (e.g., in many instances at least
25 about 40 weight percent, and usually at least about 50 weight percent of the applied coating
26 formulation is water). Water has strong absorbance bands at 1450 nm and 1940 nm.

27 A PLC-based control system 1518 provides overall supervisory control of the cigarette
28 manufacturing process. For example, the PLC-based control system 1518 can receive, process
29 and provide process control information concerning pattern application of additive material to
30 the paper web 55, inspection of the paper web, conditions associated with drying of additive
31 material that has been applied to the paper web, and rejection of cigarettes that do not meet

1 certain specifications. A suitable PLC-based system is available as SIMATIC S7-300 controller
2 model 6ES7 315-2AF03-0AB0 available from Siemens Energy and Automation, Incorporated.

3 During cigarette manufacture, when the cigarette making machine reaches the preset
4 speed, and cigarette production is underway, the cigarette making machine 10 sends a high speed
5 enable signal 1522 to the PLC 1518. The PLC processes that signal and generates an output
6 signal 1524 to a servo control system 1525, which in turn, instructs the servo motor (not shown)
7 to engage the additive applicator apparatus 70 for operation (i.e., the roller system is instructed to
8 position itself into operative engagement and begin operation for additive material application).
9 An output signal 1530 representative of the pattern sensed by the detection system 95 is sent to
10 the PLC 1518 for processing, and the PLC determines, among other things, if there is a fault and
11 if cigarette rod rejection is required. In addition, the detection system 95 sends a second signal
12 1533 (i.e., a tolerance fault) that indicates if pattern deviation (e.g., a band width deviation) is
13 within or beyond a predetermined tolerance level. If a band 1507, 1508 is missing or out of
14 tolerance (i.e., is an incorrect size), such an event is noted and the PLC determines whether to
15 reject 1536 a cigarette or shut down 1538 the cigarette making machine 10, by communication
16 with the cigarette making machine. Internal shift registers 1541 within the PLC 1518 are used to
17 keep track of the reject cigarette rod information sent to the cigarette maker control system for
18 rejection of the reject tobacco rods at the selected downstream rejection location (not shown).
19 The PLC also determines if system shut down is required (e.g., if consecutive sets of rejects
20 above a set value thereby indicating a major or catastrophic fault requiring machine operator
21 intervention), and the shutdown signal 1538 is sent to the control system (not shown) within the
22 cigarette making machine 10. The reject signal 1536 is also sent to a database 1545 for
23 recording to compute efficiency information, and any faults generated by the PLC 1518 are sent
24 through the cigarette making machine control system (not shown) to a graphical display 1550 for
25 feed back to the machine operator. Information 1551 from the cigarette making machine 10 also
26 is sent to the database 1545.

27 For a system 1500 designed to detect applied patterned bands 1507, 1508 on a paper web
28 55, such a detection system receives two input signals 1560, 1562. For example, the first signal
29 1560 can be a trigger signal that corresponds to a 1:1 ratio with the flying knife cut position 1568
30 of the continuous tobacco rod (i.e., one cut is represented by one pulse), and the second signal
31 1562 being an encoder signal that corresponds to the speed 1575 of the continuous cigarette rod.

1 In addition to the presence or absence of an applied band, the position of such a band within a
2 rod and the width of that band can be determined by the combination of these two input signals
3 1560, 1562.

4 Certain cigarette making machine components can be driven using a servo drive control
5 system 1525, or other suitable motion control means. Using servo control systems 1525, the
6 speed, acceleration rate, position, and torque of a motor (not shown) can be programmed
7 digitally. An internal encoder 1580 is integrated into the motor housing (not shown) for an
8 internal feed back for the servo motor (not shown). A servo-based drive control system
9 comprises a controller/amplifier and a servo motor that is used to match or synchronize with the
10 speed of the continuous cigarette rod in order to apply and position a desired pattern (e.g., one or
11 two bands) on what is ultimately each individual cigarette rod. This is accomplished by using
12 input signals 1585, 1587 from an encoder 1590. Signal 1585 from encoder 1590 that is
13 mechanically linked to a suitable rotating shaft (not shown) of the cigarette rod making machine
14 provides information regarding the speed and position of the cut-off knife. In addition, the
15 second signal 1587 is timed to the cut of point of the cut-off knife 1590 in order to reference the
16 cut position of each individual cigarette rod. The detector 95 detects the presence of the additive
17 material applied on the paper web, and signal 1530 also is fed to the servo controller 1580. This
18 signal is processed 1525; and the result is compared to a previously determined, pre-programmed
19 acceptance positional window. That is, the output signal 1530 concerning that detected
20 information (e.g., information regarding positioning of a band 1507 on the paper web 55) is
21 compared to that of what is expected for a paper web that is within desired specifications. The
22 servo controller 1525 also receives a signal 1598 from encoder 1575 to synchronize the operation
23 of the applicator apparatus 70 with the speed of operation of the cigarette making machine 10.
24 As such, the servo controller 1525 directs the applicator apparatus 70 to (i) correct the operation
25 of the application apparatus so as to provide corrected and proper registration by phase
26 adjustment in the servo control system, and (ii) generates out of register fault 1600 to cause
27 further processing within the PLC 1518 to determine whether to reject cigarettes that are not
28 within certain specified specifications or to shut down the cigarette making machine. For
29 example, when a band 1507 that is applied to the paper web 55 is out of registration, the servo
30 motor temporarily speeds up or slows down to allow the positioning the pattern of additive
31 material on the paper web to return back within the desired and specified registration.

Registration of the transversely positioned bands of additive material on a continuous paper web so as to be within a tolerance window is a very desirable feature when those bands are used for the production of cigarettes that meet certain standards with regards to low ignition propensity criteria. In accordance with one aspect of the present invention, registration of the patterns (e.g., bands) applied to continuous paper webs within a tolerance window can be carried out whether the patterns are applied off-line (e.g., as pre-printed patterns) or on-line (e.g., as patterns applied on the cigarette making apparatus). In particular, a 2-axes control system (i.e., a system that controls two independent motors) is used within the cigarette making apparatus in conjunction with a high speed band sensor (i.e., which is fast enough to respond to nominal cigarette making speeds). A first servo motor drives the flying knife of the cigarette making machine. The knife position at rod cut off location is derived by an encoder mechanically coupled to the cut off knife, and this signal is used as a reference point for determining the position of the band. A second servo motor drives the garniture belt and the foraminous conveyor belt, and a second encoder provides the feedback regarding cigarette making speed. The detector senses a band and the location of that band with respect to the cutoff knife. If the bands are out of registration on the cigarette rods, the servo control system typically slows down the garniture belt relative to the cut off knife so that the knife temporally will cut shorter rods until the continuous tobacco rod is in registration. This can be achieved either by speeding up the cut off knife or slowing down the garniture belt. For example, the system can be programmed to make a small adjustment per rod (e.g., such as 1 mm per cut change per rod) so as to walk the system into to registration as smoothly as possible. However, for smaller adjustments, longer periods are required to bring the cigarette rods back within the tolerance window, and hence more short cigarettes will be rejected. Such a registration system is particularly useful for making adjustments (i) during cigarette making machine start up; (ii) during machine operation after recovery from a shutdown or after a new bobbin of paper web is spliced into the machine; (iii) during normal cigarette making machine operation due to factors such as stretching of the paper web.

Referring to Figure 16, there is shown an additive application control system timing diagram for band registration on a continuous paper web. The band on the paper web is detected by a sensor, and a corresponding output signal is generated. A signal that coincides to the cut off location of a cigarette rod also is generated. A related signal corresponding to the position of the

1 rod relative to the cut-off knife location on the cigarette rod also is generated. The sensor output
2 is compared to the other two signals. Such a comparison allows for the determination of location
3 of the sensed band, and determination that the location is within an acceptable specified window.
4 Thus, for example, it is possible to consistently produce a plurality of cigarette rods, each
5 cigarette rod possessing one band having a width of 5 mm that is positioned 25 mm from the
6 lighting end of each such cigarette rod.

7 Referring to Figure 17, there is shown an additive application control system timing
8 diagram for band registration on a continuous paper web, and two bands are shown as being out
9 of position. The band on the paper web is detected by a sensor, and an output signal is generated.
10 A signal that coincides to the cut off location of a cigarette rod also is generated. A related
11 signal corresponding to the position of the rod relative to the cut-off knife location on the
12 cigarette rod also is generated. The sensor output is compared to the other two signals. Such a
13 comparison allows for the determination of location of the sensed band, and determination that
14 location is not within an acceptable specified window (i.e., whether the band is leading or
15 lagging). Thus, the servo control system can be used to adjust operation of the application
16 apparatus back into registration by phase correction. In addition, a fault signal for both leading
17 or lagging bands which do not fit into the expected registration window are generated for all the
18 out of registration rods, and sent to the PLC for processing for rejection at the proper location of
19 the system.

20 Referring to Figure 18, there is shown an additive application control system timing
21 diagram for band registration on a continuous paper web, and that band is shown to be too
22 narrow to meet specifications. The band on the paper web is detected by a sensor, and an output
23 signal is generated. A related signal corresponding to the position of the rod relative to the cut-
24 off knife location on the cigarette rod also is generated. The sensor output is compared to the
25 other two signals. Such a comparison allows for the determination of width of the sensed band,
26 and determination that width is not within an acceptable specified window. A fault signal for
27 that out of specification band is sent to the PLC for further processing for rejection or shut down
28 of the cigarette maker.

29 Referring to Figure 19, there is shown an additive application control system timing
30 diagram for band registration on a continuous paper web, and that band is shown to be too wide
31 to meet specifications. The band on the paper web is detected by a sensor, and an output signal is

1 generated. A related signal corresponding to the position of the rod relative to the cut-off knife
2 location on the cigarette rod also is generated. The sensor output is compared to the other two
3 signals. Such a comparison allows for the determination of width of the sensed band, and
4 determination that width is not within an acceptable specified window. A fault signal for that out
5 of specification band is sent to the PLC for further processing for rejection or shut down of the
6 cigarette maker.

7 Referring to Figure 20, there is shown a schematic illustration of portion of a cigarette
8 making machine 8 having yet another additive applicator apparatus representative of one aspect
9 of the present invention. A portion of a conventional PROTOS cigarette maker 10 manufactured
10 by Hauni-Werke Körber & Co. KG of Germany is shown. The maker 10 is modified to comprise
11 an additive applicator apparatus 70. The cigarette maker 10 includes a large bobbin 58 with a
12 strip 55 of paper web, or cigarette wrapper, wound thereon. Bobbin 58 is mounted for clockwise
13 rotation beneath the cigarette maker garniture 45 and printer section 1620. As the strip 55 of
14 paper web, or wrapper, is unwound from the bobbin 58, it passes around an arrangement of
15 rollers (shown as rollers 60, 61) to take up any slack in the strip 55 and maintain a certain
16 amount of tension on the paper strip.

17 After the paper strip 55 passes through the printer section 1620, it travels to the additive
18 applicator apparatus region 1625, where it first passes through a paper preheater 1628. The
19 additive applicator 70 is arranged between the bobbin 58 and the garniture 45, and preferably is
20 employed to apply bands of adhesive-type material to the moving paper strip 55. The preheater
21 1628 is preferably an infrared heater, which preheats the paper web 55 to a temperature in the
22 range of about 180° C to about 220° C. Preheating of the paper web 55 is optional, but can be
23 preferred, especially in the case of a high speed cigarette maker when preheating the paper can
24 advantageously assist in evaporating the solvent for the subsequently applied additive.

25 The preheated paper web 55 travels next to the additive applicator assembly 70,
26 sometimes broadly referred to as a “glue pot.” The additive applicator assembly 70 comprises a
27 pair of counter-rotating rollers 78, 82, which counter-rotate in the directions shown by the
28 arrows. The additive applicator assembly 70 further comprises an additive feed shoe 448. A
29 drip box 465 encloses the lower portions of the rollers 78, 82 to catch any additive that drips,
30 spatters, or is thrown by centrifugal force or otherwise from the rollers. Rollers 78, 82 are
31 engaged to counter-rotate at identical peripheral speeds, which also correspond to the speed of

1 the paper strip 55 at the point 1638 where the paper strip tangentially contacts the peripheral
2 surface of roller 82. Conventional speed control systems are useful for moving and rotating
3 machine components at precise predetermined speeds and for maintaining zero relative speed
4 between moving and rotating machine components.

5 Roller 82 is an application roller and roller 78 is a pattern roller, preferably a gravure or
6 intaglio pattern roller provided with a plurality of circumferentially-spaced transverse grooves, or
7 pockets. Additive feed shoe 448 is located between the counter-rotating rollers 78, 82 so as to
8 feed additive material to the pattern roller 78 immediately upstream of the nip between the
9 rollers. Additive material includes adhesives, such as a cigarette seam adhesive, filter plug wrap
10 adhesive, tipping paper adhesive, or the types of additive materials set forth hereinafter. As the
11 rollers 78, 82 counter-rotate, the additive material or adhesive is transferred from the transverse
12 pockets, or grooves, on the pattern roller 78 to the application roller 82 in circumferentially-
13 spaced locations on the peripheral surface of the application roller. The application roller 82 is
14 positioned to bear with a slight upward pressure against the paper strip 55 at point 1638 so as to
15 transfer the additive material to the optionally preheated paper strip 55 in longitudinally-spaced,
16 cross-directional bands (not shown) of a predetermined width and spacing.

17 After the additive material has been applied to the paper strip 55, the paper strip passes
18 through an infrared paper dryer 120 downstream of the additive applicator assembly 70 and
19 upstream of the garniture 45 of the cigarette maker 10. After passing through the dryer 120, the
20 paper strip 55 with the cross-directional bands on one surface thereof travels via another
21 arrangement of rollers 1640 to the garniture 45 where it is formed about a tobacco rod and
22 bonded along an overlapping longitudinal seam formed by the longitudinal side edges of the
23 paper strip 55. The additive material and the paper strip 55 are dried sufficiently in the infrared
24 paper dryer 120 and during passage over the roller arrangement 1640 so that the paper with the
25 spaced, cross-directional adhesive bands applied to it does not tear when it is wrapped about the
26 tobacco rod in the garniture 45.

27 The additive applicator apparatus 70 causes the additive bands to be applied to the inside
28 surface of the paper cigarette wrapper (i.e., the surface confronting the tobacco rod) as is
29 preferred. However, the additive applicator apparatus 70 can be arranged on the cigarette maker
30 10 so that the bands of additive material can be applied to the outside surface of the paper
31 cigarette wrapper, if that is desired.

1 Referring to Figure 21, there is shown a portion of a cigarette making machine assembly
2 8; and there also are shown relevant components of another representative additive applicator
3 apparatus 70. Such an applicator 70 is particularly useful for applying to a paper web 55 certain
4 types of viscous additive materials. Such additive materials useful in applications involving
5 cigarette paper include, for example, paste-type formulations of additive materials having
6 viscosities in the range of about 500,000 centipoise to about 2,500,000 centipoise.

7 Additive applicator 70 is an assembly that includes a pick-up roller 720 and a transfer
8 pressure roller 725 (or back-up roller) mounted on each side of an application roller 1800. Those
9 rollers are mounted through a front roller plate 730 secured to the front exterior region of a
10 cigarette making machine. Each of a plurality of rollers 426, 428, 430, 432 is fixedly mounted to
11 the front roller plate 730; and those rollers provide guides for a path over which the paper web 55
12 travels from a bobbin (not shown) to the additive applicator 70 and on to other regions of the
13 cigarette making machine 8.

14 The pick-up roller 720 (shown in phantom) is positioned within a reservoir 740 for the
15 additive material (not shown). The reservoir is maintained in place and secured to the front
16 roller plate 730 by bolts 1810, 1812 or other suitable connection means. The reservoir 740 is
17 connected to a source (not shown) of additive material (e.g., a formulation having the form of a
18 paste), through port 1820 near the top region of the reservoir 740. As such, a source of additive
19 material for the pick-up roller 720 is provided. If desired, the reservoir can be equipped with
20 devices for monitoring the amount of additive material that is present within that reservoir, such
21 as are described hereinbefore with reference to Figure 4. Typically, the additive material is
22 supplied through tubing (not shown), such as Tygon-type or polyethylene tubing, that feeds the
23 reservoir 740 through port 1820. The reservoir of the additive applicator 70 provides a
24 receptacle for the additive material to the point of deposit onto the pick-up roller 720.

25 A doctor blade 1822 is positioned near the pick-up roller 720 near the top region of that
26 roller. The doctor blade can be supported in a fixed position relative to the roller, or the doctor
27 blade can be adjustable, for example, by being mounted in so as to be moveable using
28 micrometer 1824. As such, the positioning of the doctor blade 1822 relative to the roll face of
29 roller 720 can be adjusted. Preferably, the doctor blade is positioned in order that additive
30 material that has been applied to the roll face of the pick-up roller is provided in the desired
31 amount. Typically, the doctor blade is positioned so as to provide a layer of additive material on

1 the roll face of the pick-up roller that has the desired thickness, both along the length and width
2 of the roll face. Typically, the doctor blade 1822 is positioned about 0.001 to about 0.002 inch
3 from the surface of the roll face of pick-up roller 720. After the additive material on the roll face
4 of the pick-up roller has been provided in the desired amount, that additive material is transferred
5 from the pick-up roller to the face of appropriate die 1840 of applicator roller 1800.

6 The pick-up roller 720 preferably is manufactured from a material that can vary, but
7 preferably is manufactured from an elastomeric type material, such as a polyurethane rubber type
8 material, a natural gum rubber, ethylene-propylene diene monomer rubber, or the like. An
9 exemplary pick-up roller has a diameter of about 50 mm to about 100 mm. For the embodiment
10 shown, the pick-up roller rotates counter-clockwise within the reservoir 740, and additive
11 material within the reservoir is deposited on the surface of that roller.

12 The pick-up roller 720 is in roll contact with a plurality of protruding applicator dies
13 1840, 1842, 1844, 1846 of application roller 1800. The application roller dies preferably are of
14 the general dimension of the pattern of additive material that is desired to be applied to the paper
15 web 55. An exemplary application roller 1800 is manufactured from stainless steel, elastomeric
16 material, or a combination of those materials. For example, the larger wheel portion of the
17 applicator roller can be manufactured from stainless steel, and the protruding dies can be
18 manufactured as replaceable inserts manufactured from relatively soft elastomeric materials.
19 Alternatively, the wheel and die component parts of the applicator roller can be manufactured
20 from a hard metal material, such as stainless steel. An exemplary applicator roller has a diameter
21 of about 50 mm to about 100 mm, and typically about 85 mm; and possesses four protruding dies
22 each of about 10 mm to about 15 mm in height, about 22 mm to about 25 mm in width, and
23 about 5 mm to about 8 mm in circumferential length. Other sizes and shapes of the dies, other
24 configurations of the dies on the roller, other roller sizes, and the composition of components
25 used to manufacture the roller, can be a matter of design choice. For the embodiment shown,
26 application roller 1800 rotates clockwise.

27 In a preferred embodiment, each roller 725, 1800 is driven independently. For example,
28 one servo drive (not shown) can control the rotation of transfer roller 725, and a second servo
29 drive (not shown) can control the applicator roller 1800. Controlling operation of the two rollers
30 725, 1800 with independent servo system allow for independent control of speeds of those two
31 rollers, and hence, the ability to tightly control the tolerances associated with application of

1 additive material to the paper web using those two rollers. Rollers that are independently
2 adjustable also are preferred in that the degree of touching of the roll faces of the respective
3 rollers during roll contact can be controlled. For example, roller lift bracket 798 is slidingly
4 adjustable about pivot plate 1806 by means of actuation by air cylinder 1805 to move roller 725
5 into and out of roll contact with paper web 55 and protruding dies 1840, 1842, 1844, 1846 of the
6 applicator roller 1800.

7 In operation, the continuous paper web 55 passes between the roll faces of the transfer
8 roller 725 and the application roller 1800. As a result of the contact experienced by the paper
9 web 55 as it travels between the roll faces of the transfer pressure roller 725 and the applicator
10 roller 1800, additive material transferred to the surfaces of the protruding dies 1840, 1842, 1844,
11 1846 from the surface of the applicator roller 720 is applied to the paper web 55 in a
12 predetermined pattern. As such, the die faces provide a type of off-set printing of additive
13 material to desired locations on the moving paper web. Movement of the transfer pressure roller
14 725 can be programmed, such as by a microprocessor associated with the operation of the cigarette
15 making machine. Such control by a signal received from the cigarette making machine can
16 allow for retraction of the pressure roller from the paper web 55 so as to not be in contact with
17 the various rollers when the cigarette making machine is not in normal operation; and as such,
18 problems associated with sticking of the paper web to various components of the applicator
19 apparatus 70 are minimized, avoided or prevented.

20 Referring to Figure 22, there is shown a portion of a cigarette making machine assembly
21 8; and there also are shown relevant components of another representative additive applicator
22 apparatus 70. Such an applicator 70 is particularly useful for applying to a paper web 55 certain
23 types of viscous additive materials. Such additive materials useful in applications involving
24 cigarette paper include, for example, paste-type formulations of additive materials having
25 viscosities in the range of about 500,000 centipoise to about 2,500,000 centipoise.

26 Additive applicator 70 is an assembly that includes a pick-up roller 720 in roll contact
27 with an applicator roller 1800. Those rollers are mounted through a front roller plate 730
28 secured to front exterior of a cigarette making machine. Each of a plurality of rollers 422, 426, is
29 fixedly mounted to the front roller plate 730; and those rollers provide guides for a path over
30 which the paper web 55 travels from a bobbin (not shown) to the additive applicator 70 and on to
31 other regions of the cigarette making machine 8.

1 The pick-up roller 720 (shown in phantom) is positioned within a reservoir 740 for the
2 additive material (not shown). The reservoir is maintained in place and secured to the front
3 roller plate 730 by bolts 1810, 1812 or other suitable connection means. The reservoir 740 is
4 connected to a source (not shown) of additive material (e.g., a formulation having the form of a
5 paste), through port 1820 near the top region of the reservoir 740. As such, a source of additive
6 material for the pick-up roller 720 is provided. Typically, the additive material is supplied
7 through tubing (not shown), such as Tygon-type tubing or polyethylene tubing, that feeds the
8 reservoir 740 through port 1820.

9 A doctor blade 1822 is positioned near the pick-up roller 720 near the top region of that
10 roller. The doctor blade can be mounted in a fixed position relative to the roll face of the roller.
11 The doctor blade also can be adjustable, for example, by being positioned so as to be movable
12 using a micrometer 1824. As such, the positioning of the doctor blade 1822 relative to the roll
13 face of roller 720 can be adjusted. Preferably, the doctor blade is positioned in order that
14 additive material that has been applied to the roll face of the pick-up roller is provided in the
15 desired amount. Typically, the doctor blade is positioned so as to provide a layer of additive
16 material on the roll face of the pick-up roller that has the desired thickness, both along the length
17 and width of the roll face. Typically, the doctor blade 1822 is positioned about 0.001 to about
18 0.002 inch from the surface of the roll face of pick-up roller 720. After the additive material on
19 the roll face of the pick-up roller has been provided in the desired amount, that additive material
20 is transferred from the roll face of the pick-up roller to appropriate locations on the paper web
21 55.

22 The pick-up roller 720 preferably is manufactured from a material that can vary, that can
23 be, e.g., a soft material or a hard material, but preferably is manufactured from an elastomeric
24 type material, such as a polyurethane rubber type material, or other suitable material. An
25 exemplary pick-up roller is described previously with reference to Figure 21. The pick-up roller
26 rotates clockwise (for the embodiment shown) within the reservoir 740, and additive material
27 within the reservoir is deposited on the surface of the roll face of that roller.

28 The pick-up roller 720 is in roll contact with protruding applicator cams 1840, 1842,
29 1844, 1846 of application roller 1800. The application roller cams are of the general dimension
30 of the pattern of additive material that is desired to be applied to the paper web 55. An

1 exemplary application roller 1800 is described previously with reference to Figure 21. For the
2 embodiment shown, application roller 1800 rotates counter-clockwise.

3 In a preferred embodiment, each roller 725, 1800 is driven independently. For example,
4 one servo drive (not shown) can control the rotation of transfer roller 725, and a second servo
5 drive (not shown) can control the applicator roller 1800. Controlling operation of the two rollers
6 725, 1800 with independent servo systems allow for independent control of speeds of those two
7 rollers, and hence, the ability to tightly control the tolerances associated with application of
8 additive material to the paper web using those two rollers.

9 In operation, the continuous paper web 55 passes between the roll faces of the pick-up
10 roller 720 and the application roller 1800. As a result of the contact experienced by the paper
11 web 55 as it travels between pick-up roller 720 and the applicator roller 1800, additive material
12 transferred by the surfaces of the protruding cams 1840, 1842, 1844, 1846 from the surface of
13 the applicator roller 720 is applied to the paper web 55 in a predetermined pattern. That is, the
14 protruding applicator roller cams on the side of paper web, opposite the pick-up roller and the
15 additive material, cause periodic deflection of the paper web toward the pick-up roller; and as
16 such, additive material is transferred from the surface of the pick-up roller to the paper web in a
17 controlled manner as a result of the camming action of the applicator roller. The paper web 55 is
18 routed in a manner such that the paper web has a tendency to move upwards and away from the
19 surface of the applicator pick-up roller when the various cams are not deflecting that paper web
20 downwards. As a result, control of the location of the application of additive material on the
21 paper web can be carried out.

22 Referring to Figure 23, there is shown a portion of a cigarette making machine assembly
23 8 of the present invention. In particular, there is shown an additive applicator apparatus 70
24 representative of one aspect of the present invention. Such an additive applicator 70 is
25 particularly useful for applying to a paper web 55 additive materials (not shown) that can have
26 relatively wide ranges of viscosities (e.g., formulations of additive materials that can be
27 considered to have forms ranging from liquid to relatively thick pastes).

28 Additive applicator 70 is an assembly that includes a pick-up roller 78 and a transfer
29 roller 82 mounted adjacent to each other, and mounted through a roller support plate 400 on the
30 exterior front face of the cigarette making machine assembly 8. Descriptions of various relevant
31 components of such an additive applicator apparatus 70 are set forth previously with reference to

Figures 3-7, 21 and 22. Various components of such an additive applicator 70 are manufactured from suitable metals, such as cast or machined aluminum or stainless steel. The pick-up roller 78 and the transfer roller 82 preferably are manufactured from hardened stainless steel. An exemplary pick-up roller has a diameter of about 80 mm to about 130 mm, and a total roll face width of about 55 mm to about 80 mm. An exemplary transfer roller has a diameter of about 80 mm to about 130 mm, and a total roll face width of about 35 mm to about 50 mm. Several fixed guide posts, air bars or rotatable guide rollers 420, 422, 424, are suitably fixedly mounted; such as to either the front roller plate 400 or the chassis of the cigarette making machine assembly 8, depending upon the desired location of those guide posts or rollers. Those guide posts or rollers provide the path over which the paper web 55 travels from a bobbin (not shown) in the direction shown by arrow 1900, past the additive applicator 70, and on to other downstream destinations of the cigarette making machine assembly.

The additive applicator 70 also includes a manifold 444 positioned above an additive material reservoir (not shown). That reservoir is located in the nip zone above pick-up roller 78 and transfer roller 82, and the general size and shape of that reservoir is determined by the configuration of those rollers and control block 1902. As such, a type of puddle of additive material is provided in the nip zone about those rollers. The positioning of the control block 1902 is maintained through the positioning of a reservoir front arm 452 and a reservoir rear arm (not shown). Those reservoir arms are positioned above the pick-up roller 78, and are movable about pivot pin 1907. The control block 1902 can be positioned up or down through the use of an adjustable stop arm 1912. In addition to assisting in providing the boundaries of the reservoir, the control block also provides internal and external porting (not shown) for supply additive material (not shown) from an external source (not shown) and removal of excess additive material for recycling or disposal.

The manifold 444 is attached to a manifold pivot plate (not shown), which is attached to the front roller plate 400. Such attachment leaves the manifold 444 with the capability of moving upward and downward about a manifold pivot pin (not shown). The manifold 444 can be maintained in place during operation of the system through force provided by an air cylinder 1915. Tubing (not shown), such as Tygon-type or polyethylene tubing, or other suitable supply means, is connected to the manifold 444 and originates at a source of additive material (not shown) to provide an input of additive material to the reservoir (not shown). The assembly also

1 includes a collection pot 465 positioned adjacent to and slightly below the pick-up roller 78. The
2 collection pot 465 serves as a temporary collection location for excess additive material removed
3 from the pick-up roller 78. If desired, the reservoir can be equipped with devices for monitoring
4 the amount of additive material that is present within that reservoir, such as are described
5 hereinbefore with reference to Figure 4. The reservoir of the additive applicator 70 provides a
6 receptacle for the additive material to the point of deposit onto the pick-up roller 78.

7 Against the front side face of the transfer roller 82 is positioned a scraper 864. A
8 corresponding scraper (not shown) is positioned against the back side face of the transfer roller
9 82. The scrapers are formed as downwardly extending arms of the control block 1902. As such,
10 excess additive material on the surfaces of the side faces of the transfer roller 82 is scraped from
11 that roller as it passes the scraper. That material then exits at least one outlet port (not shown),
12 which is located within the control block 1902. Typically, two ports, one on each of the front
13 and rear sides of the transfer roller 82, are employed. Then, the excess material is removed
14 through tubes (not shown) to be recycled or discarded. A diaphragm pump (not shown) or other
15 type of suitable means for supply of vacuum can be used to evacuate excess additive material
16 from the system. As such, both side faces of the transfer roller 82 are subjected to surface
17 treatment by two scraper pieces arranged along the side of that roller, so as to remove
18 undesirable excess additive formulation from those surfaces, and hence, maintain those surfaces
19 relatively clean by maintaining those surfaces relatively free of build up of coating formulation.
20 If desired, further surface treatments of either or both of the pick-up roller and transfer roller
21 with air streams, water spray, scrapes or brushes can be employed to assist in maintaining the
22 surfaces of those rollers clean and to assist in reducing the generation of heat caused by friction.

23 The transfer roller 82 and the pick-up roller 78 are positioned into operative engagement
24 with one another using a roller pressure plate 480. The roller pressure plate 480 is operably
25 connected to an air cylinder 484, or other suitable means for applying force to rollers 78, 82.
26 The air cylinder 484 utilizes compressed air to force the roller pressure plate 480 about a
27 pressure plate pivot shaft 488 into and out of engagement with the transfer roller 82. That plate
28 480 applies pressure to the collection pot 465 to move that collection pot into engagement with a
29 bearing housing (not shown) on the shaft of pick-up roller 78. Thus, intimate roll contact
30 between the roll faces of transfer roller 82 and pick-up roller 78 can be provided. Movement of
31 the roller pressure plate 480 to engage and disengage the pick-up roller 78 with the transfer roller

82 can programmed, and as such a microprocessor associated with the operation of the cigarette making machine can be used to control movement of that plate 480.

In operation, pick-up roller 78 is rotated counter-clockwise and the transfer roller 82 is rotated clockwise. Hence, additive material introduced into the upper nip region (e.g., reservoir) between the rotating pick-up roller 78 and counter-rotating transfer roller 82 fills a grooved or recessed region (not shown) in the roll face of pick-up roller, and is retained on the roll face of the transfer roller in the region thereof adjacent that grooved or recessed region. As such, there is provided an assembly and method for continuously providing a predetermined supply of additive material to a predetermined region of the roll face of the transfer roller 82.

Additive applicator 70 is an assembly that also includes an application roller 1800 and a transfer pressure roller 725 (or back-up roller) mounted on each side of an application roller 82. Typically, the back-up roller 725 is manufactured from an elastomeric material; and exemplary back-up rollers are those that are used in cigarette making machines that are commercially available. Those rollers are mounted through a front roller plate 400 that is secured to the front exterior region of a cigarette making machine 8. Other back-up roller configurations, such as those types of configurations described previously with reference to Figures 5, 6 and 21, also can be employed. The moving paper web 55 is passed between the roll faces of the application roller 1800 and the back-up roller 725.

The manner of arranging and mounting the various rollers can vary. For example, any or all of the rollers can be designed so as to be mounted using a tapered shaft and spindle type of configuration.

The transfer roller 82 is in roll contact with a plurality (e.g., twelve, or other selected number) of protruding applicator dies 1840, 1842, 1844, 1846 of application roller 1800. The application roller dies preferably are of the general dimension of the pattern of additive material that is desired to be applied to the paper web 55. An exemplary application roller 1800 is manufactured from stainless steel, elastomeric material, or a combination of those materials. For example, larger central wheel portion 1920 of the applicator roller can be manufactured from stainless steel, and the protruding dies within the outer roll face 1925 can be shaped manufactured from a relatively soft or flexible elastomeric material. Alternatively, the protruding dies can be manufactured as replaceable inserts manufactured from relatively soft or flexible elastomeric materials. Exemplary elastomeric type materials, are materials such as a

polyurethane rubber type material, a natural gum rubber, silicon rubber, and ethylene-propylene diene monomer rubber. Representative protruding dies and associated components fashioned from elastomeric materials can be provided from polyurethane rubber materials of the types available as Cytec Compound #TV-8070 Polyurethane 60-65 Durometer "A", Cytec Compound #TV-8050 Polyurethane 40-45 Durometer "A", and Cytec Compound #TV-8090 Polyurethane 80-85 Durometer "A", from Cytec Inc. Alternatively, the wheel and die component parts of the applicator roller can be manufactured from a hard metal material, such as stainless steel. An exemplary applicator roller has a diameter of about 100 mm to about 200 mm, and typically about 130 mm to about 170 mm; and possesses about four to about sixteen protruding dies each of about 1 mm to about 4 mm in radial height, about 22 mm to about 25 mm in width, and about 5 mm to about 8 mm in circumferential length. Such an applicator roller can be used to apply to one surface of a web of cigarette paper wrapping material spaced bands that are oriented transversely to the longitudinal axis of that paper web. Other sizes and shapes of the dies, other configurations of the dies on the roller, other roller sizes, and the composition of components used to manufacture the roller, can be a matter of design choice. For the embodiment shown, application roller 1800 rotates counter-clockwise.

For a representative embodiment, the pick-up roller 78 and the transfer roller 82 each have diameters of about 103 mm. The transfer roller 82 has a roll face having a width of about 40 mm. The pick-up roller 78 has a roll face having a width of about 68 mm, and a groove having a width of about 22.5 mm is located about equidistant from each side of that roller and circumscribes the entire roll face of that roller. The groove has a depth that can vary, and the depth of a representative groove is about 0.001 inch to about 0.003 inch. The application roller has a width of about 23 mm; and has an inner roller having a diameter of about 130 mm, and an outer face of polyurethane-type rubber material having a radial thickness of about 7 mm, and extending from the outer face are twelve equally spaced dies each having a radial height of about 2.5 mm and a circumferential length of about 6 mm. Such an application roller 1800 can be used to apply to a cigarette paper wrapper an adhesive formulation in the form of spaced bands that are arranged to extend across at least a portion of the width of that wrapper, and that have widths of about 23 mm and lengths of about 6 mm.

In a preferred embodiment, each of the transfer roller 82 and the application roller 1800 is driven independently. For example, one servo drive (not shown) can control the rotation of

1 application roller 1800, and a second servo drive (not shown) can control the transfer roller 82.
2 The rotation of the pick-up roller 78 relative to the rotation of the transfer roller 78 can be tightly
3 controlled (e.g., in terms of a timed speed of rotation) in the general manner described previously
4 with reference to Figure 4. Controlling operation of the various rollers with independent servo
5 systems allows for independent control of speeds of the two supply rollers (e.g., the pick-up and
6 transfer rollers) relative to the application roller, and hence, the ability to tightly control the
7 tolerances associated with application of additive material to the paper web using a multi-roller
8 system. Additionally, it is preferred that rollers that are independently adjustable, in that the
9 degree of touching of the roll faces of the respective rollers during roll contact can be controlled.
10 If desired, each of the application roller 1800, transfer roller 82 and pick-up roller 78 each can be
11 independently operated using three separate servo systems.

12 In operation, during the process of cigarette manufacture, the pick-up roller 78 is rotated
13 counter-clockwise, and the transfer roller 82 is rotated clock-wise. Those rollers are engaged in
14 contact by pressure supplied by the pressure plate 480. Additive material (not shown) is fed
15 from a source (not shown) to the manifold 444, and from the manifold to the reservoir (not
16 shown). As such additive material is introduced into the upper nip region between the roll faces
17 of the pick-up roller 78 and the transfer roller 82. Due to the continuous groove (not shown) in
18 the roll face of the pick-up roller, additive material has a tendency to fill that groove; and due to
19 the maintained roll contact between the pick-up and transfer rollers, additive material is applied
20 as a continuous stripe on a portion of the roll face of the transfer roller in the region thereof
21 adjacent the groove of the pick-up roller. The application roller 1800, which is in roll contact
22 with the transfer roller, rotates counter-clockwise. Hence, coating formulations, such as mixtures
23 incorporating modified starches and water, can be applied in the desired amount and in the
24 desired manner, on the appropriate region of the roll face of transfer roller, and that formulation
25 then can be efficiently and effectively transferred from the transfer roller to the appropriate
26 regions of the application roller. The continuous paper web 55 passes between the roll faces of
27 the transfer roller 1800 and the back-up roller 725. As a result of the contact experienced by the
28 paper web 55 as it travels between the roll faces of the transfer pressure roller 725 and the
29 applicator roller 1800, additive material transferred to the surfaces of the protruding dies 1840,
30 1842, 1844, 1846 from the surface of the applicator roller is applied to the paper web 55 in a
31 predetermined pattern. As such, the die faces provide a type of off-set printing of additive

1 material to desired locations on the moving paper web. As a result, the additive material on the
2 surface of the application roller 1800 is transferred to the inside surface of the advancing paper
3 web 55 at locations corresponding to the pattern on the roller face of the application roller.
4 Operation and interaction of the transfer roller 82 and application roller 1800 relative to one
5 another are such that the transfer roller supplies the desired amount of additive material to the die
6 faces of the application roller. Operation and interaction of the die faces of the application roller
7 1800 and the paper web 55 are such that additive material on successive die faces is applied at
8 predetermined and desired locations of the paper web. That is, the paper web 55 is supplied at a
9 very high rate of speed, and hence, the various rollers also rotate as a correspondingly high rate
10 of speed. The paper web 55 having additive material applied thereto then is advanced to
11 downstream locations of the cigarette making machine.

12 Referring to Figure 24, there is shown a pick-up roller 78 that is representative of the type
13 of pick-up roller described previously with reference to Figure 24. The pick-up roller 78
14 possesses a roll face 1950, as well as a circumferentially extending groove 1955 that extends
15 completely around the periphery of the roll face. The width of the groove can vary, and can be
16 designed to provide a desired amount of additive material formulation (not shown). The depth of
17 the groove can also vary, and can be designed to provide a desired amount of additive material
18 formulation (not shown). The groove 1955 most preferably is positioned such that the recess in
19 the roll face of the roller is located between front side roll face surface 1960 and rear side roll
20 face surface 1962. As such, in operation, the roll face (not shown) of the transfer roller (not
21 shown) is in roll contact with side roll face surfaces 1960, 1962 of the pick-up roller 78; and a
22 hollow region (not shown) is formed in the region where those rollers are in roll contact, due to
23 the presence of the groove 1955 in the roll face 1950 of the pick-up roller. Although a preferred
24 embodiment possesses one continuous groove, other groove designs can be employed. For
25 example, a series of continuous grooves, grooves forming the shape of a grid, or other type of
26 pattern, can be employed.

27 Referring to Figure 25, there is shown an alternate type of application roller 1800 that is
28 representative of the type of application roller described previously with reference to Figure 23.
29 Such an application roller can be used as the application roller in the types of applicator systems
30 described previously with reference to Figures 21 and 22. The application roller possesses a
31 plurality of spaced dies 1840, 1842, 1844, 1846 positioned at desired locations on the roll face

1 1965 (e.g., the peripheral surface) of the roller 1800. The dies are provided from cylinders of
2 elastomeric material positioned in semi-circular types of recesses formed in the large central
3 region of the roller. A removable side plate 1969 helps assist in maintaining the dies in place on
4 the roll face of the roller.

5 Referring to Figure 26, there is shown an alternate type of application roller 1800 that is
6 representative of the type of application roller described previously with reference to Figure 23.
7 Such an application roller can be used as the application roller in the types of applicator systems
8 described previously with reference to Figures 21 and 22. The application roller possesses a
9 plurality of spaced dies 1840, 1842, 1844, 1846 positioned at desired locations on the roll face
10 1965 of the roller 1800. The dies 1840, 1842, 1844, 1846 are provided from cylinders of
11 elastomeric material positioned in outwardly extending insertion regions 1980, 1981, 1982,
12 1983, respectively, formed in the large central region of the roller. A removable side plate (not
13 shown) helps assist in maintaining the dies in place on the roll face of the roller.

14 Referring to Figure 27, there is shown an alternate type of application roller 1800 that is
15 representative of the type of application roller described previously with reference to Figure 23.
16 Such an application roller can be used as the application roller in the types of applicator systems
17 described previously with reference to Figures 21 and 22. The application roller possesses a
18 plurality of spaced dies 1840, 1842, 1844, 1846 positioned at desired locations on the roll face
19 1965 of the roller 1800. The dies are provided from cylinders of elastomeric material positioned
20 in corresponding semi-circular types of recesses formed in the large central region of the roller.
21 A removable side plate 1969 helps assist in maintaining the dies in place on the roll face of the
22 roller.

23 Referring to Figure 28, there is shown an alternate type of application roller 1800 that is
24 representative of the type of application roller described previously with reference to Figure 23.
25 Such an application roller can be used as the application roller in the types of applicator systems
26 described previously with reference to Figures 21 and 22. The application roller possesses a
27 plurality of spaced dies 1840, 1842, 1844, 1846 positioned at desired locations on the roll face
28 1965 of the roller 1800. The dies are provided from shaped pieces of elastomeric material
29 positioned in corresponding formed recesses 1980, 1981, 1982, 1983 (e.g., wedge-shaped types
30 of recesses) formed in the large central region of the roller. A removable side plate (not shown)
31 helps assist in maintaining the dies in place on the roll face of the roller.

1 The various components, systems and methods can be employed individually, or in
2 various combinations with one another. In one regard, a cigarette making machine assembly
3 can incorporate an on-line additive application system for a paper web, a modified finger rail
4 assembly and/or a modified garniture entrance cone, a registration system, an inspection system,
5 and heating/cooling control system, each of which are of the type that have been described as
6 various aspects of the present invention. In another regard, for example, the on-line additive
7 application systems can be incorporated into cigarette making machine assemblies without any
8 or all of those other components that have been described as various aspects of the present
9 invention. In another regard, for example, the modified finger rail assemblies and/or the
10 modified garniture entrance cones can be incorporated into cigarette making machine assemblies
11 that do not possess any or all of those other components or features that have been described as
12 various aspects of the present invention. In addition, for example, cigarette making machine
13 assemblies possessing on-line application systems, modified finger rail assemblies and/or
14 modified garniture entrance cones and heating/cooling control systems of the types of the present
15 invention can be employed without using registration systems and/or inspection systems.
16 Likewise, for example, cigarette making machine assemblies possessing registration systems
17 and/or inspection systems of the types of the present inventions can be employed without using
18 those modified finger rail assemblies, modified garniture entrance cones and/or heating/cooling
19 control systems that have been described as various aspects of the present invention.

20 The various aspects of the present invention, whether employed individually or in some
21 combination, offer several advantages and improvements to conventional systems and methods
22 for cigarette manufacture. The present invention allows a cigarette manufacturer to apply
23 predetermined and discrete amounts of an additive material to a continuous advancing strip of a
24 paper web at desired locations on that paper web, during the manufacture of a continuous
25 cigarette rod using conventional types of cigarette making equipment and methodologies. Of
26 particular interest are bands of additive material that are positioned perpendicularly to the
27 longitudinal axis of the paper web, and those bands can be positioned so as to extend across less
28 than the total width of that paper web. As such, the location of additive material can be
29 controlled so as to not be located in the lap zone of the continuous cigarette rod (e.g., where the
30 side seam adhesive is applied). Thus, for example, a continuous paper web having a width of
31 about 27 mm and used to provide a cigarette rod having a circumference of about 24.5 mm (i.e.,

1 such that the lap zone has a width of about 2.5 mm) can have a band applied to that web such
2 that the band is not located within the lap zone where side seam adhesive is applied; and as such,
3 such a band can have a transversely extending length of about 22 mm to about 24.5 mm. The
4 present invention allows a cigarette manufacturer to apply to paper webs additive formulations
5 that have a wide range of chemical and physical properties, and that are provided for application
6 in a wide variety of forms (e.g., a wide range of viscosities). The finger rail modifications, the
7 garniture entrance cone modifications and the heating/cooling control systems of the present
8 invention provide a manufacturer of cigarettes an efficient and effective way to produce
9 cigarettes having additive material applied to the wrapping materials of those cigarette rods in an
10 on-line fashion, during the manufacture of those cigarette rods. That is, the present invention
11 advantageously provides a means for retaining an additive material on a paper web and
12 preventing transfer of the additive material to the surfaces of various components of a cigarette
13 making machine. In addition, the present invention allows a manufacturer of cigarettes to apply
14 additive materials to paper webs without adversely affecting the physical properties and integrity
15 of that paper web to any significant degree. Registration of patterns (e.g., bands) applied to the
16 paper wrapping materials of tobacco rods promotes the ability of cigarette manufacturers to
17 provide consistent quality cigarette rods, and the ability to control the properties of cigarettes
18 through on-line production techniques offers advantages over cigarettes that are manufactured
19 using pre-printed paper wrapping materials. The present invention also provides a manufacturer
20 of cigarettes with the ability to ensure the production of high quality cigarettes with applied
21 patterns registered in the desired locations of those cigarettes.

22 Certain preferred paper wrapping materials used in carrying out the present invention are
23 useful for the manufacture of cigarettes designed to exhibit reduced ignition propensity. That is,
24 cigarettes incorporating certain wrapping materials, when placed on a flammable substrate, tend
25 to self extinguish before burning that substrate. Of particular interest are those cigarettes
26 possessing tobacco rods manufactured using appropriate wrapping materials possessing bands
27 composed of appropriate amounts of appropriate components so as to have the ability to meet
28 certain cigarette extinction criteria.

29 The paper wrapping material that is further processed to provide the patterned wrapping
30 material can have a wide range of compositions and properties. The selection of a particular
31 wrapping material will be readily apparent to those skilled in the art of cigarette design and

1 manufacture. Typical paper wrapping materials are manufactured from fibrous materials, and
2 optional filler materials, to form so-called “base sheets.” Wrapping materials of the present
3 invention can be manufactured without significant modifications to the production techniques or
4 processing equipment used to manufacture those wrapping materials.

5 Typical wrapping material base sheets suitable for use as the circumscribing wrappers of
6 tobacco rods for cigarettes have basis weights that can vary. Typical dry basis weights of base
7 sheets are at least about 15 g/m^2 , and frequently are at least about 20 g/m^2 ; while typical dry
8 basis weights do not exceed about 80 g/m^2 , and frequently do not exceed about 60 g/m^2 . Many
9 preferred wrapping material base sheets have basis weights of less than 50 g/m^2 , and even less
10 than 40 g/m^2 . Certain preferred paper wrapping material base sheets have basis weights between
11 about 20 g/m^2 and about 30 g/m^2 .

12 Typical wrapping material base sheets suitable for use as the circumscribing wrappers of
13 tobacco rods for cigarettes have inherent porosities that can vary. Typical base sheets have
14 inherent porosities that are at least about 5 CORESTA units, usually are at least about 10
15 CORESTA units, often are at least about 15 CORESTA units, and frequently are at least about
16 20 CORESTA units. Typical base sheets have inherent porosities that are less than about 200
17 CORESTA units, usually are less than about 150 CORESTA units, often are less than about 85
18 CORESTA units, and frequently are less than about 70 CORESTA units. A CORESTA unit is a
19 measure of the linear air velocity that passes through a 1 cm^2 area of wrapping material at a
20 constant pressure of 1 centibar. See, CORESTA Publication ISO/TC0126/SC I N159E (1986).
21 The term “inherent porosity” refers to the porosity of that wrapping material itself to the flow of
22 air. A particularly preferred paper wrapping material base sheet is composed of wood pulp and
23 calcium carbonate, and exhibits an inherent porosity of about 20 to about 50 CORESTA units.

24 Typical paper wrapping material base sheets suitable for use as the circumscribing
25 wrappers of tobacco rods for cigarettes incorporate at least one type of fibrous material, and can
26 incorporate at least one filler material, in amounts that can vary. Typical base sheets include
27 about 55 to about 100, often about 65 to about 95, and frequently about 70 to about 90 percent
28 fibrous material (which most preferably is a cellulosic material); and about 0 to about 45, often
29 about 5 to about 35, and frequently about 10 to about 30 percent filler material (which most
30 preferably is an inorganic material); based on the dry weight of that base sheet.

1 The wrapping material incorporates a fibrous material. The fibrous material can vary.
2 Most preferably, the fibrous material is a cellulosic material, and the cellulosic material can be a
3 lignocellulosic material. Exemplary cellulosic materials include flax fibers, hardwood pulp,
4 softwood pulp, hemp fibers, esparto fibers, kenaf fibers, jute fibers and sisal fibers. Mixtures of
5 two or more types of cellulosic materials can be employed. For example, wrapping materials can
6 incorporate mixtures of flax fibers and wood pulp. The fibers can be bleached or unbleached.
7 Other fibrous materials that can be incorporated within wrapping materials include microfibers
8 materials and fibrous synthetic cellulosic materials. See, for example, U.S. Patent Nos.
9 4,779,631 to Durocher and 5,849,153 to Ishino. Representative fibrous materials, and methods
10 for making wrapping materials therefrom, are set forth in U.S. Patent Nos. 2,754,207 to Schur et
11 al; and 5,474,095 to Allen et al.; and PCT WO 01/48318.

12 The wrapping material normally incorporates a filler material. Certain types of filler
13 materials are set forth in PCT WO 03/043450. Preferably, the filler material has the form of
14 essentially water insoluble particles. Additionally, the filler material normally incorporates
15 inorganic components. Filler materials incorporating calcium salts are particularly preferred.
16 One exemplary filler material has the form of calcium carbonate, and the calcium carbonate most
17 preferably is used in particulate form. See, for example, U.S. Patent Nos. 4,805,644 to Hampl;
18 5,161,551 to Sanders; and 5,263,500 to Baldwin et al.; and PCT WO 01/48,316. Other filler
19 materials include agglomerated calcium carbonate particles, calcium tartrate particles,
20 magnesium oxide particles, magnesium hydroxide gels; magnesium carbonate-type materials,
21 clays, diatomaceous earth materials, titanium dioxide particles, gamma alumina materials and
22 calcium sulfate particles. See, for example, U.S. Patent Nos. 3,049,449 to Allegrini; 4,108,151
23 to Martin; 4,231,377 to Cline; 4,450,847 to Owens; 4,779,631 to Durocher; 4,915,118 to
24 Kaufman; 5,092,306 to Bokelman; 5,109,876 to Hayden; 5,699,811 to Paine; 5,927,288 to
25 Bensalem; 5,979,461 to Bensalem; and 6,138,684 to Yamazaki; and European Patent
26 Application 357359. Certain filler-type materials that can be incorporated into the wrapping
27 materials can have fibrous forms. For example, components of the filler material can include
28 materials such as glass fibers, ceramic fibers, carbon fibers and calcium sulfate fibers. See, for
29 example, U.S. Patent Nos. 2,998,012 to Lamm; 4,433,679 to Cline; and 5,103,844 to Hayden et
30 al.; PCT WO 01/41590; and European Patent Application 1,084,629. Mixtures of filler materials
31 can be used. For example, filler material compositions can incorporate mixtures of calcium

1 carbonate particles and precipitated magnesium hydroxide gel, mixtures of calcium carbonate
2 particles and calcium sulfate fibers, or mixtures of calcium carbonate particles and magnesium
3 carbonate particles.

4 There are various ways by which the various additive components can be added to, or
5 otherwise incorporated into, the base sheet. Certain additives can be incorporated into the
6 wrapping material as part of the paper manufacturing process associated with the production of
7 that wrapping material. Alternatively, additives can be incorporated into the wrapping material
8 using size press techniques, spraying techniques, printing techniques, or the like. Such
9 techniques, known as “off-line” techniques, are used to apply additives to wrapping materials
10 after those wrapping materials have been manufactured. Various additives can be added to, or
11 otherwise incorporated into, the wrapping material simultaneously or at different stages during or
12 after the paper manufacturing process.

13 The base sheets can be treated further, and those base sheets can be treated so as to impart
14 a change to the overall physical characteristics thereof and/or so as to introduce a change in the
15 overall chemical compositions thereof. For example, the base sheet can be electrostatically
16 perforated. See, for example, U.S. Patent No. 4,924,888 to Perfetti et al. The base sheet also can
17 be embossed, for example, in order to provide texture to major surface thereof. Additives can be
18 incorporated into the wrapping material for a variety of reasons. Representative additives, and
19 methods for incorporating those additives to wrapping materials, are set forth in U.S. Patent No.
20 5,220,930 to Gentry, which is incorporated herein by reference. See, also, U.S. Patent No.
21 5,168,884 to Baldwin et al. Certain components, such as alkali metal salts, can act a burn control
22 additives. Representative salts include alkali metal succinates, citrates, acetates, malates,
23 carbonates, chlorides, tartrates, propionates, nitrates and glycolates; including sodium succinate,
24 potassium succinate, sodium citrate, potassium citrate, sodium acetate, potassium acetate,
25 sodium malate, potassium malate, sodium carbonate, potassium carbonate, sodium chloride,
26 potassium chloride, sodium tartrate, potassium tartrate, sodium propionate, potassium
27 propionate, sodium nitrate, potassium nitrate, sodium glycolate and potassium glycolate; and
28 other salts such as monoammonium phosphate. Certain alkali earth metal salts also can be used.
29 See, for example, U.S. Patent Nos. 2,580,568 to Matthews; 4,461,311 to Matthews; 4,622,983 to
30 Matthews; 4,941,485 to Perfetti et al.; 4,998,541 to Perfetti et al.; and PCT WO 01/08514.
31 Certain components, such as metal citrates, can act as ash conditioners or ash sealers. See, for

1 example, European Patent Application 1,084,630. Other representative components include
2 organic and inorganic acids, such as malic, levulinic, boric and lactic acids. See, for example,
3 U.S. Patent No. 4,230,131 to Simon. Other representative components include catalytic
4 materials. See, for example, U.S. Patent No. 2,755,207 to Frankenburg. Typically, the amount
5 of chemical additive does not exceed about 3 percent, often does not exceed about 2 percent, and
6 usually does not exceed about 1 percent, based on the dry weight of the wrapping material to
7 which the chemical additive is applied. For certain wrapping materials, the amount of certain
8 additive salts, such as burn chemicals such as potassium citrate and monoammonium phosphate,
9 preferably are in the range of about 0.5 to about 0.8 percent, based on the dry weight of the
10 wrapping material to which those additive salts are applied. Relatively high levels of additive
11 salts can be used on certain types of wrapping materials printed with printed regions that are very
12 effective at causing extinction of cigarettes manufactured from those wrapping materials.
13 Exemplary flax-containing cigarette paper wrapping materials having relatively high levels of
14 chemical additives have been available as Grade Names 512, 525, 527, 540, 605 and 664 from
15 Schweitzer-Mauduit International. Exemplary wood pulp-containing cigarette paper wrapping
16 materials having relatively high levels of chemical additives have been available as Grade
17 Names 406 and 419 from Schweitzer-Mauduit International.

18 Flavoring agents and/or flavor and aroma precursors (e.g., vanillin glucoside and/or ethyl
19 vanillin glucoside) also can be incorporated into the paper wrapping material. See, for example,
20 U.S. Patent Nos. 4,804,002 to Herron; and 4,941,486 to Dube et al. Flavoring agents also can be
21 printed onto cigarette papers. See, for example, the types of flavoring agents used in cigarette
22 manufacture that are set forth in Gutcho, *Tobacco Flavoring Substances and Methods*, Noyes
23 Data Corp. (1972) and Leffingwell et al., *Tobacco Flavoring for Smoking Products* (1972).

24 Films can be applied to the paper. See, for example, 4,889,145 to Adams; U.S. Patent
25 No. 5,060,675 to Milford et al., and PCT WO 02/43513 and PCT WO 02/055294. Catalytic
26 materials can be incorporated into the paper. See, for example, PCT WO 02/435134.

27 Typical paper wrapping materials that can be used in carrying out the present invention
28 are manufactured under specifications directed toward the production of a wrapping material
29 having an overall generally consistent composition and physical parameters. For those types of
30 wrapping materials, the composition and parameters thereof preferably are consistent when
31 considered over regions of each of the major surfaces of those materials. However, typical

1 wrapping materials tend to have a “two-sided” nature, and thus, there can be changes in the
2 composition and certain physical parameters of those materials from one major surface to the
3 other.

4 Though less preferred, the wrapping material can be manufactured using a paper making
5 process adapted to provide a base web comprising multiple layers of cellulosic material. See,
6 U.S. Patent No. 5,143,098 to Rogers et al.

7 Much less preferred paper wrapping materials can have compositions and/or properties
8 that differ over different regions of each of their major surfaces. The wrapping material can have
9 regions of increased or decreased porosity provided by control of the composition of that
10 material, such as by controlling the amount or type of the filler. The wrapping material can have
11 regions of increased or decreased air permeability provided by embossing or perforating that
12 material. See, for example, U.S. Patent No. 4,945,932 to Mentzel et al. The wrapping material
13 can have regions (e.g., predetermined regions, such as bands) treated with additives, such as
14 certain of the aforementioned salts. However, wrapping materials having a patterned nature are
15 not necessary when various aspects of the present invention are used to apply patterns to those
16 wrapping materials using on-line pattern application techniques.

17 Paper wrapping materials suitable for use in carrying out the present invention are
18 commercially available. Representative cigarette paper wrapping materials have been available
19 as Ref. Nos. 419, 454, 456, 460 and 473 Ecusta Corp.; Ref. Nos. Velin 413, Velin 430, VE 825
20 C20, VE 825 C30, VE 825 C45, VE 826 C24, VE 826 C30 and 856 DL from Miquel; Tercig
21 LK18, Tercig LK24, Tercig LK38, Tercig LK46 and Tercig LK60 from Tervakoski; and Velin
22 Beige 34, Velin Beige 46, Velin Beige 60, and Ref. Nos. 454 DL, 454 LV, 553 and 556 from
23 Wattens. Exemplary flax-containing cigarette paper wrapping materials have been available as
24 Grade Names 105, 114, 116, 119, 170, 178, 514, 523, 536, 520, 550, 557, 584, 595, 603, 609,
25 615 and 668 from Schweitzer-Mauduit International. Exemplary wood pulp-containing cigarette
26 paper wrapping materials have been available as Grade Names 404, 416, 422, 453, 454, 456,
27 465, 466 and 468 from Schweitzer-Mauduit International.

28 The composition of the additive material or coating formulation can vary. Generally, the
29 composition of the coating is determined by the ingredients of the coating formulation.
30 Preferably, the coating formulation has an overall composition, and is applied in a manner and in
31 an amount, such that the physical integrity of the wrapping material is not adversely affected

1 when the coating formulation is applied to selected regions of the wrapping material. It also is
2 desirable that components of the coating formulation not introduce undesirable sensory
3 characteristics to the smoke generated by a smoke article incorporating a wrapping material
4 treated with that coating formulation. Thus, suitable combinations of various components can
5 act to reduce the effect of coatings on sensory characteristics of smoke generated by the smoking
6 article during use. Preferred coatings provide desirable physical characteristics to cigarettes
7 manufactured from wrapping materials incorporating those coatings. Preferred coatings also can
8 be considered to be adhesives, as it is desirable for those coatings to remain in intimate contact
9 with (e.g., to adhere to or otherwise remain secured to) desired locations on the wrapping
10 material.

11 Examples of coating formulations and representative components thereof are set forth in
12 U.S. Patent Nos. 4,889,145 to Adams; and 5,060,675 to Milford et al.; U.S. Patent Application
13 2003/0145869 to Kitao et al.; U.S. Patent Application 2003/0150466 to Kitao et al.; and U.S.
14 Patent Application Serial No. 09/892,834, filed June 27, 2001; PCT WO 02/043513; PCT WO
15 02/055294; and European Patent Application 1,234,514. Other coating formulations are
16 described herein.

17 The coating formulation most preferably includes a film-forming agent. The film-
18 forming agent most preferably is a polymeric material or resin. Exemplary film-forming agents
19 include alginates (e.g., sodium alginate or ammonium alginate, including those alginates
20 available as Kelcosol from Kelco), pectins (e.g., including those available as TIC Pretested HM
21 from TIC Gums), derivatives of cellulose (e.g., carboxymethylcellulose including the Aqualon
22 sodium carboxymethylcellulose CMC from Hercules Incorporated, and other polymeric
23 materials such as hydroxypropylcellulose and hydroxyethylcellulose), ethylene vinyl acetate
24 copolymers, guar gum (e.g., including Type M, Type MM, Type MM high viscosity from
25 Frutarom; and Ticagel from TIC Gums), xanthan gum (e.g., including Keltrol from Kelco),
26 starch (e.g., corn starch, rice starch and dextrin), modified starch (e.g., oxidized tapioca starch
27 and oxidized corn starch), polyvinyl acetate and polyvinyl alcohol. Suitable combinations of
28 various film-forming agents also can be employed. Exemplary blends include water-based
29 blends of ethylene vinyl acetate copolymer emulsion and polyvinyl alcohol. Other exemplary
30 blends are water-based blends provided by mixing starches or modified starches with emulsion
31 polymers or copolymers.

1 The solvent or liquid carrier for the coating formulation can vary. The solvent can be a
2 liquid having an aqueous character, and can include relatively pure water. An aqueous liquid is a
3 suitable solvent or carrier for film-forming agents such as water-based emulsions, starch-based
4 materials, sodium carboxymethylcellulose, ammonium alginate, guar gum, xanthan gum, pectins,
5 polyvinyl alcohol and hydroxyethylcellulose. Starch-based materials are film-forming agents
6 that are composed of starch or components derived from starch. It is preferred that the solvent
7 not be a non-aqueous solvent, such as ethanol, *n*-propyl alcohol, *iso*-propyl alcohol, ethyl acetate,
8 *n*-propyl acetate, *iso*-propyl acetate, toluene, and the like. Formulations that incorporate solvents
9 in amounts and forms such that those solvents do not adversely affect the quality of the wrapping
10 material (e.g., by causing swelling of the fibers of the wrapping material, by causing puckering
11 of the wrapping material, or by causing wrinkling of the wrapping material) are particularly
12 preferred.

13 Generally, the selection of solvent depends upon the nature of the film-forming
14 polymeric material, and the particular polymeric material that is selected readily dissolves (i.e., is
15 soluble) or is highly dispersible in a highly preferred solvent. Although not all components of
16 the coating formulation are necessarily soluble in the liquid carrier, it is most preferable that the
17 film-forming polymeric material be soluble (or at least highly dispersible) in that liquid. By
18 “soluble” in referring to the components of the coating formulation with respect to the liquid
19 solvent is meant that the components for a thermodynamically stable mixture when combined
20 with the solvent, have a significant ability to dissolve in that solvent, and do not form precipitates
21 to any significant degree when present in that solvent.

22 The coating formulation also can include a filler material. Exemplary filler materials can
23 be the essentially water insoluble types of filler materials previously described. Preferred filler
24 materials have a finely divided (e.g., particulate) form. Typical fillers are those that have particle
25 sizes that are less than about 3 microns in diameter. Typical particle sizes of suitable fillers
26 range from about 0.3 micron to 2 microns in diameter. The filler materials can have a variety of
27 shapes. Exemplary filler materials are those that are composed of inorganic materials including
28 metal particles and filings, calcium carbonate (e.g., precipitated-type fillers, including those
29 having a prismatic form), calcium phosphate, clays (e.g., attapulgite clay), talc, aluminum oxide,
30 mica, magnesium oxide, calcium sulfate, magnesium carbonate, magnesium hydroxide,
31 aluminum oxide and titanium dioxide. See, for example, the types of filler materials set forth in

1 U.S. Patent No. 5,878,753 to Peterson et al. Representative calcium carbonate fillers are those
2 available as Albacar PCC, Albafil PCC, Albaglos PCC, Opacarb PCC, Jetcoat PCC and
3 Calopake F PCC from Specialty Minerals, Inc. Exemplary filler materials also can be composed
4 of organic materials including starches, modified starches and flours (e.g., rice flour), particles of
5 polyvinyl alcohol, particles of tobacco (e.g., tobacco dust), and other like materials. The filler
6 material also can be fibrous cellulosic materials. See, for example, U.S. Patent No. 5,417,228 to
7 Baldwin et al. Although less preferred, alternate fillers can include carbon-based materials (e.g.,
8 graphite-type materials, carbon fiber materials and ceramics), metallic materials (e.g., particles of
9 iron), and the like. The filler material also can be a water soluble salt (e.g., potassium chloride,
10 sodium chloride, potassium citrate, sodium citrate, calcium chloride or magnesium chloride).

11 The coating formulations can incorporate other ingredients in addition to the
12 aforementioned coating materials. Those ingredients can be dispersed or suspended within the
13 coating formulation. Those other ingredients can be employed in order to provide specific
14 properties or characteristics to the wrapping material. Those ingredients can be preservatives
15 (e.g., potassium sorbate), humectants (e.g., ethylene glycol and propylene glycol), pigments,
16 dyes, colorants, burn promoters and enhancers, burn retardants and inhibitors, plasticers (e.g.,
17 dibutyl phthalate, polyethylene glycol, polypropylene glycol and triacetin), sizing agents, syrups
18 (e.g., high fructose corn syrup), flavoring agents (e.g., ethyl vanillin and caryophyllene oxide),
19 sugars (e.g., rhamnose), flavor precursors, hydrate materials, such as metal hydrates (e.g., borax,
20 magnesium sulfate decahydrate, sodium silicate pentahydrate and sodium sulfate decahydrate),
21 viscosity reducing agents (e.g., urea), and the like. Certain of those ingredients are soluble in the
22 solvent of the coating formulation (e.g., certain salts, acids and bases are soluble in solvents such
23 as water). Certain of those ingredients are insoluble in the solvent of the coating formulation
24 (e.g., particles of metallic materials are insoluble in most of the solvents used for coating
25 formulations).

26 The coating formulation typically has a liquid, syrup or paste form, and is applied as
27 such. Depending upon the actual ingredients that are combined with the solvent, the coating
28 formulation has the form of a solution, an emulsion (e.g., a water-based emulsion), or a liquid
29 having solid materials dispersed therein. Generally, the film-forming agent is dissolved or
30 dispersed in a suitable solvent to form the coating formulation. Certain other optional
31 ingredients also are dissolved, dispersed or suspended in that formulation. Additionally, optional

1 filler material also is dispersed within that formulation. Preferably, the filler material is
2 essentially insoluble and essentially chemically non-reactive with the solvent, at least at those
3 conditions at which the formulation is employed.

4 The relative amounts of the various components of the coating formulation can vary.
5 Typically, the coating formulation includes at least about 30 percent solvent, usually at least
6 about 40 percent solvent, and often at least about 50 percent solvent, based on the total weight of
7 that formulation. Typically, the amount of solvent within the coating formulation does not
8 exceed about 95 percent, usually does not exceed about 90 percent, and often does not exceed
9 about 85 percent, based on the total weight of that formulation. Most preferably, the coating
10 formulation includes at least about 0.5 percent film-forming agent, usually at least about 1
11 percent film-forming agent, and often at least about 2 percent film-forming agent, based on the
12 total weight of that formulation. Typically, the amount of film-forming agent within the coating
13 formulation does not exceed about 60 percent, usually does not exceed about 50 percent, and
14 often does not exceed about 40 percent, based on the total weight of that formulation. Typically,
15 the coating formulation includes at least about 3 percent of the optional filler material, usually at
16 least about 5 percent filler material, and often at least about 10 percent filler material, based on
17 the total weight of that formulation. Typically, the amount of optional filler material within the
18 coating formulation does not exceed about 35 percent, usually does not exceed about 30 percent,
19 and often does not exceed about 25 percent, based on the total weight of that formulation.

20 The amounts of other optional components of the coating formulation can vary. The
21 amount of plasticizer often ranges from about 0.5 percent to about 5 percent, preferably about 2
22 to about 3 percent, based on the total weight of the formulation. The amount of humectant often
23 ranges from about 1 percent to about 5 percent, preferably about 2 to about 3 percent, based on
24 the total weight of the formulation. The amount of wetting agent often ranges from about 0.5
25 percent to about 2 percent, preferably about 0.8 to about 1 percent, based on the total weight of
26 the formulation. The amount of preservative often ranges from about 0.01 percent to about 0.3
27 percent, preferably about 0.5 percent, based on the total weight of the formulation. The amount
28 of burn chemical often ranges from about 1 percent to about 15 percent, preferably about 5 to
29 about 10 percent, based on the total weight of the formulation. The amount of viscosity reducing
30 agent often ranges from about 1 percent to about 10 percent, preferably about 2 percent to about
31 6 percent, based on the total weight of the formulation. The amount of burn chemical often

1 ranges from about 1 percent to about 15 percent, preferably about 5 to about 10 percent, based on
2 the total weight of the formulation. The amount of metal hydrate often ranges from about 3
3 percent, usually at least about 5 percent, and often at least about 10 percent, based on the total
4 weight of that formulation; but the amount of metal hydrate usually does not exceed about 35
5 percent, often does not exceed about 30 percent, and frequently does not exceed about 25
6 percent, based on the total weight of that formulation.

7 Flavoring agents can be incorporated into the coating formulations. Preferably, the
8 flavoring agents exhibit sensory characteristics that can be described as having notes that are
9 sweet, woody, fruity, or some combination thereof. The flavoring agents preferably are
10 employed in amounts that depend upon their individual detection thresholds. Typically, the
11 flavoring agents are employed in sufficient amounts so as to mask or ameliorate the off-tastes
12 and malodors associated with burning paper. Combinations of flavoring agents (e.g., a flavor
13 package) can be employed in order to provide desired overall sensory characteristics to smoke
14 generated from the smoking articles incorporating those flavoring agents. Most preferably, those
15 flavoring agents are employed in amounts and manners so that the sensory characteristics of
16 those flavoring agents are hardly detectable; and those flavoring agents do not adversely affect
17 the overall sensory characteristics of smoking article into which they are incorporated. Preferred
18 flavoring agents can be incorporated into printing formulations, have low vapor pressures, do not
19 have a tendency to migrate or evaporate under normal ambient conditions, and are stable under
20 the processing conditions experienced by wrapping materials of the present invention.

21 Exemplary flavoring agents that provide sweet notes include ethyl vanillin, vanillin, heliotropin,
22 methylcyclopentenolone; and those flavoring agents typically are employed in amounts of 0.001
23 to about 0.01 percent, based on the total weight of the coating formulation into which they are
24 incorporated. An exemplary flavoring agent that provides woody notes includes caryophyllene
25 oxide; and that flavoring agent typically is employed in amounts of 0.2 to about 0.6 percent,
26 based on the total weight of the coating formulation into which it is incorporated. Exemplary
27 flavoring agents that provide fruity notes include ketones such as 4-hydroxyphenyl-2-butanone
28 and lactones such as *gamma*-dodecalactone; and those flavoring agents typically are employed in
29 amounts of 0.001 to about 0.1 percent, based on the total weight of the coating formulation into
30 which they are incorporated.

1 Certain additive materials can be applied to the wrapping material in the form of a
2 coating formulation that is in a so-called "solid polymer" form. That is, film-forming materials,
3 such as ethylene vinyl acetate copolymers and certain starches, can be mixed with other
4 components of the coating formation, and applied to the wrapping material without the necessity
5 of dissolving those film-forming materials in a suitable solvent. Typically, solid polymer coating
6 formulations are applied at elevated temperatures relative to ambient temperature; and the
7 viscosities of the film-forming materials of those heated coating formulations typically have an
8 extremely wide range of viscosities.

9 One suitable formulation for an additive material for a paper web incorporates a water-
10 based coating that is employed in liquid form, and that coating is an adhesive formulation of R. J.
11 Reynolds Tobacco Company used as a cigarette seam adhesive and designated as CS-1242. The
12 CS-1242 formulation is a water emulsion-based adhesive consisting of about 87 to about 88
13 weight percent ethylene vinyl acetate copolymer emulsion sold under the designation Resyn 32-
14 0272 by National Starch & Chemical Company, and about 12 to about 13 weight percent
15 adhesive concentrate stabilizer of R. J. Reynolds Tobacco Company known as AC-9. The AC-9
16 adhesive concentrate stabilizer consists of about 92 weight percent water and about 8 weight
17 percent polyvinyl alcohol resin available as Celvol 205 from Celanese Chemicals. Such a
18 formulation exhibits a viscosity of about 400 centipoise. If desired, the formulation can contain
19 dyes or pigments for aesthetic purposes or to facilitate automated inspection of paper wrapping
20 materials to which the formulation is applied. Such a formulation is particularly suitable for use
21 with an application system of the type described previously with reference to Figures 3 and 4.

22 Certain preferred formulations incorporate starch. Typical formulations incorporate
23 about 30 to about 55 weight percent starch, about 35 to about 55 weight percent water, and about
24 0 to about 35 weight percent other components (e.g., such as the types of additive components
25 and processing aids that have been described previously). If desired, mixtures of starch and
26 emulsion polymers, or mixtures of starch and emulsion copolymers, can be used. For example, a
27 formulation can be provided by mixing starch in water with a polyvinylalcohol-stabilized
28 emulsion polymer or copolymer (e.g., ethylene vinylacetate); or by mixing starch in water with a
29 surfactant-stabilized emulsion polymer or copolymer.

30 One suitable formulation for an additive material for a paper web is a starch-based
31 aqueous formulation. A representative formulation includes about 10 weight percent sodium

1 chloride, about 0.5 weight percent potassium sorbate, about 35 weight percent oxidized tapioca
2 starch available as Flo-Max 8 from National Starch & Chemical Company, about 20 weight
3 percent calcium carbonate, and about 34.5 weight percent water. Such a formulation exhibits a
4 viscosity of about 1,000 centipoise. If desired, the formulation can contain dyes or pigments for
5 aesthetic purposes or to facilitate automated inspection of paper wrapping materials to which the
6 formulation is applied. Such a formulation is particularly suitable for use with an application
7 system of the type described previously with reference to Figures 3 and 4.

8 Another suitable formulation for an additive material for a paper web is a starch-based
9 aqueous formulation. A representative formulation includes about 5 weight percent sodium
10 chloride, about 0.5 weight percent potassium sorbate, about 49.8 weight percent oxidized tapioca
11 starch available as Flo-Max 8 from National Starch & Chemical Company, and about 44.7
12 weight percent water. Preferably, the mixture is heated at an elevated temperature (e.g., about
13 170°F) for a period of time (e.g., about 10 minutes) sufficient to result in the formation of a
14 desirable paste. Such a formulation exhibits a viscosity in the range of about 200,000 centipoise
15 to about 2,000,000 centipoise. The viscosity of such a formulation increases over time after
16 initial manufacture. If desired, the formulation can contain dyes or pigments for aesthetic
17 purposes or to facilitate automated inspection of paper wrapping materials to which the
18 formulation is applied. Such a formulation is particularly suitable for use with an application
19 system of the type described previously with reference to Figures 5-7.

20 Another suitable formulation for an additive material for a paper web is a starch-based
21 aqueous formulation. A representative formulation includes about 10 weight percent sodium
22 chloride, about 0.5 weight percent potassium sorbate, about 40 weight percent oxidized tapioca
23 starch available as Flo-Max 8 from National Starch & Chemical Company, and about 49.5
24 weight percent water. Preferably, the mixture is heated at an elevated temperature (e.g., about
25 170°F) for a period of time (e.g., about 10 minutes) sufficient to result in the formation of a
26 desirable paste. After manufacture and storage, such a formulation exhibits a viscosity in the
27 range of about 200,000 centipoise to about 2,000,000 centipoise. The viscosity of such a
28 formulation gradually increases over time after initial manufacture. If desired, the formulation
29 can contain dyes or pigments for aesthetic purposes or to facilitate automated inspection of paper
30 wrapping materials to which the formulation is applied. Such a formulation is particularly

1 suitable for use with an application system of the type described previously with reference to
2 Figures 5-7.

3 Another suitable formulation for an additive material for a paper web is a starch-based
4 aqueous formulation. A representative formulation includes about 10 weight percent sodium
5 chloride, about 40 weight percent oxidized tapioca starch available as Flo-Max 8 from National
6 Starch & Chemical Company, and about 50 weight percent water. Preferably, the mixture is
7 heated at an elevated temperature (e.g., about 165°F) for a short period of time (e.g., about 10
8 minutes). Such a formulation exhibits an initial viscosity in the range of about 2,000 centipoise
9 to about 10,000 centipoise, and often about 3,000 to about 6,000 centipoise. The viscosity of
10 such a formulation can have a tendency to increase over time after initial manufacture; and
11 typically can increase to over 100,000 centipoise. If desired, the formulation can contain dyes or
12 pigments for aesthetic purposes or to facilitate automated inspection of paper wrapping materials
13 to which the formulation is applied. Surfactants and soaps also can be incorporated into such a
14 formulation, in order to assist in retarding viscosity growth over time. For such a type of
15 formulation, it is desirable to employ the formulation such that the solids content thereof is at
16 least in the range of about 44 to about 47 weight percent. Such a formulation is particularly
17 suitable for use with an application system of the type described previously with reference to
18 Figure 23.

19 The amount of coating formulation that is applied to the paper wrapping material can
20 vary. Typically, coating of the wrapping material provides a coated wrapping material having an
21 overall dry basis weight (i.e., the basis weight of the whole wrapping material, including coated
22 and uncoated regions) of at least about 1.05 times, often at least about 1.1 times, and frequently
23 at least about 1.2 times, that of the dry basis weight of that wrapping material prior to the
24 application of coating thereto. Typically, coating of the wrapping material provides a coated
25 paper having an overall dry basis weight of not more about 1.4 times, and often not more than
26 about 1.3 times, that of the dry basis weight of the wrapping material that has the coating applied
27 thereto. Typical overall dry basis weights of those wrapping materials are about 20 g/m² to
28 about 40 g/m²; preferably about 25 g/m² to about 35 g/m². For example, a paper wrapping
29 material having a dry basis weight of about 25 g/m² can be coated in accordance with the present
30 invention to have a resulting overall dry basis weight of about 26.5 g/m² to about 35 g/m², and
31 often about 28 g/m² to about 32 g/m².

1 The dry weights of the coated regions of wrapping material of the present invention can
2 vary. For wrapping materials that are used for the manufacture of cigarettes designed to meet
3 certain cigarette extinction test criteria, it is desirable that the wrapping materials have sufficient
4 coating formulation applied thereto in the form of appropriately shaped and spaced bands in
5 order that the dry weight of additive material applied to those wrapping materials totals at least
6 about 1 pound/ream, often at least about 2 pounds/ream, and frequently at least about 3
7 pounds/ream; while the total dry weight of that applied additive material normally does not
8 exceed about 10 pounds/ream.

9 Typical coated regions of paper wrapping materials of the present invention that are
10 suitable for use as the circumscribing wrappers of tobacco rods for cigarettes have inherent
11 porosities that can vary. Typically, the inherent porosities of the coated regions of the wrapping
12 materials are less than about 8.5 CORESTA units, usually are less than about 8 CORESTA units,
13 often are less than about 7 CORESTA units, and frequently are less than about 6 CORESTA
14 units. Typically, the inherent porosities of the coated regions of the wrapping materials are at
15 least about 0.1 CORESTA unit, usually are at least about 0.5 CORESTA unit, often are at least
16 about 1 CORESTA unit. Preferably, the inherent porosities of the coated regions of the
17 wrapping materials, particularly those wrapping materials that are used for the manufacture of
18 cigarettes designed to meet certain cigarette extinction test criteria, are between about 0.1
19 CORESTA unit and about 4 CORESTA units.

20 The paper wrapping material of the present invention can have can be coated in patterns
21 having predetermined shapes. The coating can have the form of bands, cross directional lines or
22 bands (including those that are perpendicular to the longitudinal axis of the wrapping material),
23 stripes, grids, longitudinally extending lines, circles, hollow circles, dots, ovals, checks, spirals,
24 swirls, helical bands, diagonally crossing lines or bands, triangles, hexagonals, honeycombs,
25 ladder-type shapes, zig zag shaped stripes or bands, sinusoidal shaped stripes or bands, square
26 wave shaped stripes or bands, patterns composed of coated regions that are generally "C" or "U"
27 shaped, patterns composed of coated regions that are generally "E" shaped, patterns composed of
28 coated regions that are generally "S" shaped, patterns composed of coated regions that are
29 generally "T" shaped, patterns composed of coated regions that are generally "V" shaped,
30 patterns composed of coated regions that are generally "W" shaped, patterns composed of coated
31 regions that are generally "X" shaped, patterns composed of coated regions that are generally

1 “Z” shaped, or other desired shapes. Combinations of the foregoing shapes also can used to
2 provide the desired pattern.

3 The relative sizes or dimensions of the various shapes and designs can be selected as
4 desired. For example, shapes of coated regions, compositions of the coating formulations, or
5 amounts or concentrations of coating materials, can change over the length of the wrapping
6 material. The relative positioning of the printed regions can be selected as desired. For example,
7 wrapping materials that are used for the production of cigarettes designed to meet certain
8 cigarette extinction test criteria, the pattern most preferably has the form of spaced continuous
9 bands that are aligned transversely or cross directionally to the longitudinal axis of the wrapping
10 material. However, cigarettes can be manufactured from wrapping materials possessing
11 discontinuous bands positioned in a spaced apart relationship. For wrapping materials of those
12 cigarettes, it is most preferred that discontinuous bands (e.g., bands that are composed of a
13 pattern, such as a series of dots, grids or stripes) cover at least about 70 percent of the surface of
14 the band area or region of the wrapping material.

15 Preferred wrapping materials possess coatings in the form of bands that extend across the
16 wrapping material, generally perpendicular to the longitudinal axis of the wrapping material.
17 The widths of the individual bands can vary, as well as the spacings between those bands.
18 Typically, those bands have widths of at least about 0.5 mm, usually at least about 1 mm,
19 frequently at least about 2 mm, and most preferably at least about 3 mm. Typically, those bands
20 have widths of up to about 8 mm, usually up to about 7 mm. Preferred bands have widths of
21 about 4 mm to about 7 mm. Such bands can be spaced apart such that the spacing between the
22 bands is at least about 10 mm; often at least about 15 mm, frequently at least about 20 mm, often
23 at least about 25 mm, in certain instances at least about 30 mm, and on occasion at least about 35
24 mm; but such spacing usually does not exceed about 50 mm.

25 There are several factors that determine a specific coating pattern for a wrapping material
26 of the present invention. It is desirable that the components of the coating formulations applied
27 to wrapping materials not adversely affect to any significant degree (i) the appearance of
28 cigarettes manufactured from those wrapping materials, (ii) the nature or quality of the smoke
29 generated by those cigarettes, (iii) the desirable burn characteristics of those cigarettes, or (iv) the
30 desirable performance characteristics of those cigarettes. It also is desirable that wrapping
31 materials having coating formulations applied thereto not introduce undesirable off-taste, or

1 otherwise adversely affect the sensory characteristics of the smoke generated by cigarettes
2 manufactured using those wrapping materials. In addition, preferred cigarettes of the present
3 invention do not have a tendency to undergo premature extinction, such as when lit cigarettes are
4 held in the smoker's hand or when placed in an ashtray for a brief period of time.

5 Cigarettes designed to meet certain cigarette extinction test criteria can be produced from
6 wrapping materials of the present invention. Banded regions on a wrapping material are
7 produced using additive materials that are effective in reducing the inherent porosity of the
8 wrapping material in those regions. Film-forming materials and fillers applied to the wrapping
9 material in those banded regions are effective in increasing the weight of the wrapping material
10 in those regions. Filler materials that are applied to the wrapping material in those banded
11 regions are effective in decreasing the burn rate of the wrapping materials in those regions.
12 Typically, when wrapping materials of relatively high inherent porosity are used to manufacture
13 cigarettes, those wrapping materials possess relatively high weight bands that introduce a
14 relatively low inherent porosity to the banded regions. Film-forming materials have a tendency
15 to reduce the porosity of the wrapping material, whether or not those materials are used in
16 conjunction with fillers. However, coatings that combine porosity reduction with added coating
17 weight to wrapping materials also are effective in facilitating extinction of cigarettes
18 manufactured from those wrapping materials. Low porosity in selected regions of a wrapping
19 material tends to cause a lit cigarette to extinguish due to the decrease in access to oxygen for
20 combustion for the smokable material within that wrapping material. Increased weight of the
21 wrapping material also tends to cause lit cigarette incorporating that wrapping material to
22 extinguish. As the inherent porosity of the wrapping material increases, it also is desirable to (a)
23 select a film-forming material so as to cause a decrease the inherent porosity of the coated region
24 of the wrapping material and/or (b) provide a coating that provides a relatively large amount of
25 added weight to the coated region of the wrapping material.

26 Paper wrapping materials of the present invention are useful as components of smoking
27 articles such as cigarettes. Preferably, one layer of the wrapping material of the present
28 invention is used as the wrapping material circumscribing the smokable material, and thereby
29 forming the tobacco rod of a cigarette. In one regard, it is preferable that the wrapping material
30 possesses the coated regions located on the "wire" side thereof, and the "wire" side of that
31 wrapping material forms the inner surface of the circumscribing wrapping material of the

1 tobacco rod. Typically, the “felt” side of the wrapping material is used as the visible outer
2 surface of the tobacco rod. The terms “wire side” and “felt side” in referring to the major
3 surfaces of paper sheet are readily understood as terms of art to those skilled in the art of paper
4 and cigarette manufacture.

5 Cigarettes of the present invention possessing tobacco rods manufactured using certain
6 appropriately treated wrapping materials of the present invention, when tested using the
7 methodology set forth in the Cigarette Extinction Test Method by the National Institute of
8 Standards and Technology (NIST), Publication 851 (1993) using 10 layers of Whatman No. 2
9 filter paper, meet criteria requiring extinction of greater than about 50 percent, preferably greater
10 than about 75 percent, and most preferably about 100 percent, of cigarettes tested. Certain
11 cigarettes of the present invention possessing tobacco rods manufactured using certain
12 appropriately treated wrapping materials of the present invention, when tested using the
13 methodology set forth in the methodology set forth in ASTM Designation: E 2187-02b using 10
14 layers of Whatman No. 2 filter paper, meet criteria requiring extinction of greater than about 50
15 percent, preferably greater than about 75 percent, and most preferably about 100 percent, of
16 cigarettes tested. Preferably, each cigarette possesses at least one band located in a region of its
17 tobacco rod such that the band is capable of providing that cigarette with the ability to meet those
18 cigarette extinction criteria. For a tobacco rod of a particular length incorporating a wrapping
19 material possessing bands that are aligned transversely to the longitudinal axis of the wrapping
20 material in a spaced apart relationship, the ratio of the length of the tobacco rod to the sum of the
21 width of a band and the distance between the bands is 1 to 2, preferably about 1.1 to about 1.4,
22 and most preferably about 1.2.

23 For an exemplary full flavor cigarette having a tobacco rod length of about 63 mm and a
24 filter element length of about 21 mm, cross directional bands of about 6 mm width can be spaced
25 at about 20 mm intervals on the wrapping materials used to manufacture those cigarettes.
26 Alternatively, for those types of cigarettes, bands of about 4 mm width can be spaced at about 22
27 mm intervals on the wrapping materials used to manufacture those cigarettes. Alternatively, for
28 those types of cigarettes, bands of about 6 mm width can be spaced at about 39 mm intervals.
29 For an exemplary full flavor cigarette having a tobacco rod length of about 70 mm and a filter
30 element length of about 30 mm, cross directional bands of about 6 mm width can be spaced at
31 about 44 mm intervals on the wrapping materials used to manufacture those cigarettes. For an

1 exemplary ultra low tar cigarette having a tobacco rod length of about 57 mm and a filter
2 element length of about 27 mm, cross directional bands of about 7 mm width can be spaced at
3 about 20 mm intervals. Alternatively, for those types of cigarettes, bands of about 6 mm width
4 can be spaced at about 33 mm intervals, or at about 39 mm intervals, on the wrapping materials
5 used to manufacture those cigarettes. For an exemplary ultra low tar cigarette having a tobacco
6 rod length of about 68 mm and a filter element length of about 31 mm, cross directional bands of
7 about 6 mm width can be spaced at about 44 mm intervals on the wrapping materials used to
8 manufacture those cigarettes. Full flavor cigarettes are classified as those that yield about 14 mg
9 or more of FTC “tar.” Ultra low tar cigarettes are classified as those that yield less than about 7
10 mg of FTC “tar.” Those cigarettes, have tobacco rods having appropriate wrapping materials
11 possessing bands composed of appropriate amounts of appropriate components have the ability
12 to meet the aforementioned cigarette extinction criteria.

13 Cigarettes of the present invention can be manufactured from a variety of components,
14 and can have a wide range of formats and configurations. Typical cigarettes of the present
15 invention having cross directional bands applied to the wrapping materials of the tobacco rods of
16 those cigarettes have static burn rates (i.e., burn rates of those cigarettes under non-puffing
17 conditions) of about 50 to about 60 mg tobacco rod weight per minute, in the non-banded regions
18 of those cigarettes. Typical cigarettes of the present invention having cross directional bands
19 applied to the wrapping materials of the tobacco rods of those cigarettes have static burn rates
20 (i.e., burn rates of those cigarettes under non-puffing conditions) of less than about 50 mg
21 tobacco rod weight per minute, preferably about 40 to about 45 mg tobacco rod weight per
22 minute, in the banded regions of those cigarettes.

23 The tobacco materials used for the manufacture of cigarettes of the present invention can
24 vary. Descriptions of various types of tobaccos, growing practices, harvesting practices and
25 curing practices are set for in *Tobacco Production, Chemistry and Technology*, Davis et al.
26 (Eds.) (1999). The tobacco normally is used in cut filler form (e.g., shreds or strands of tobacco
27 filler cut into widths of about 1/10 inch to about 1/60 inch, preferably about 1/20 inch to about
28 1/35 inch, and in lengths of about 1/4 inch to about 3 inches). The amount of tobacco filler
29 normally used within a cigarette ranges from about 0.6 g to about 1 g. The tobacco filler
30 normally is employed so as to filler the tobacco rod at a packing density of about 100 mg/cm³ to
31 about 300 mg/cm³, and often about 150 mg/cm³ to about 275 mg/cm³. Tobaccos can have a

1 processed form, such as processed tobacco stems (e.g., cut-rolled or cut-puffed stems), volume
2 expanded tobacco (e.g., puffed tobacco, such as propane expanded tobacco and dry ice expanded
3 tobacco (DIET)), or reconstituted tobacco (e.g., reconstituted tobaccos manufactured using
4 paper-making type or cast sheet type processes).

5 Typically, tobacco materials for cigarette manufacture are used in a so-called “blended”
6 form. For example, certain popular tobacco blends, commonly referred to as “American blends,”
7 comprise mixtures of flue-cured tobacco, burley tobacco and Oriental tobacco, and in many
8 cases, certain processed tobaccos, such as reconstituted tobacco and processed tobacco stems.
9 The precise amount of each type of tobacco within a tobacco blend used for the manufacture of a
10 particular cigarette brand varies from brand to brand. See, for example, *Tobacco Encyclopedia*,
11 Voges (Ed.) p. 44-45 (1984), Browne, *The Design of Cigarettes*, 3rd Ed., p.43 (1990) and
12 *Tobacco Production, Chemistry and Technology*, Davis et al. (Eds.) p. 346 (1999). Other
13 representative tobacco blends also are set forth in U.S. Patent Nos. 4,924,888 to Perfetti et al.;
14 5,056,537 to Brown et al.; and 5,220,930 to Gentry; and Bombick et al., *Fund. Appl. Toxicol.*,
15 39, p. 11-17 (1997). See, also, PCT WO 02/37990.

16 If desired, in addition to the aforementioned tobacco materials, the tobacco blend of the
17 present invention can further include other components. Other components include casing
18 materials (e.g., sugars, glycerin, cocoa and licorice) and top dressing materials (e.g., flavoring
19 materials, such as menthol). The selection of particular casing and top dressing components is
20 dependent upon factors such as the sensory characteristics that are desired, and the selection of
21 those components will be readily apparent to those skilled in the art of cigarette design and
22 manufacture. See, Gutcho, *Tobacco Flavoring Substances and Methods*, Noyes Data Corp.
23 (1972) and Leffingwell et al., *Tobacco Flavoring for Smoking Products* (1972).

24 Smoking articles also can incorporate at least one flavor component within the side seam
25 adhesive applied to the wrapping material during the manufacture of the tobacco rods. That is,
26 for example, various flavoring agents can be incorporated in a side seam adhesive CS-2201A
27 available from R. J. Reynolds Tobacco Company, and applied to the seam line of the wrapping
28 material. Those flavoring agents are employed in order to mask or ameliorate any off-taste or
29 malodor provided to the smoke generated by smoking articles as a result of the use of the
30 wrapping materials of the present invention, such as those wrapping materials having coating
31 formulations incorporating certain cellulosic-based or starch-based components applied thereto.

1 Exemplary flavors include methyl cyclopentenolone, vanillin, ethyl vanillin, 4-
2 parahydroxyphenyl-2-butanone, *gamma*-undecalactone, 2-methoxy-4-vinylphenol, 2-methoxy-4-
3 methylphenol, 5-ethyl-3-hydroxy-4-methyl-2(5H)-furanone, methyl salicylate, clary sage oil and
4 sandalwood oil. Typically, such types of flavor components are employed in amounts of about
5 0.2 percent to about 6.0 percent, based on the total weight of the adhesive and flavor
6 components.

7 Exemplary cigarettes, and exemplary components, parameters and specifications thereof,
8 are described in U.S. Patent No. 5,220,930 to Gentry; PCT WO 02/37990 and U.S. Patent
9 Application 2002/0166563; which are incorporated herein by reference.

10 Although the present invention has been described with reference to particular
11 embodiments, it should be recognized that these embodiments are merely illustrative of the
12 principles of the present invention. Those of ordinary skill in the art of smoking article design
13 and manufacture will appreciate that the various systems, equipment and methods may be
14 constructed and implemented in other ways and embodiments. Accordingly, the description
15 herein should not be read as limiting the present invention, as other embodiments also fall within
16 the scope of the present invention.
